CHAPTER IX

FINANCIAL PLANS FOR EMPLOYEES

EMPLOYEE INVESTMENTS IN COMPANY SECURITIES

BY GLENN A. BOWERS, *Industrial Relations Counselors, Inc.*

In the field of employee investments, a cash reserve which may be drawn upon in times of emergency is perhaps first in importance. This need is filled for large numbers of workers through savings bank accounts. Home ownership is still widely regarded in some communities as a basic need for a place to live, although the changing housing conditions in congested centers have lessened the extent of this need. When one or both of these needs have been met, the employee may next turn his attention toward income-bearing securities. The issuance in recent years of corporate stocks in small denominations has made possible the entry of workers into the field of investment securities. It was as a part of this situation that employee stock ownership plans came into being.

Employees' stock ownership, like various other industrial relations projects, received a considerable impetus during the war. The widespread prosperity which industry enjoyed made stocks generally a desirable investment for the employee and new capital was needed in the expansion which accompanied increased business activity. The end of the World War and the subsequent business depression of 1921 terminated the special conditions underlying many stock subscription plans and it became necessary to adjust them to new situations.

In order to determine the place which an employees' stock subscription plan may hold in the industrial relations program of a given company it is essential that it be examined from several angles. Every stock purchase plan is inherently a part of a wider movement—the increasing dissemination of capital. A specific plan in order to be fully satisfactory must be sound financially both from the standpoint of the company and the employee subscribers. The latter should be able to compare it favorably with insurance and savings bank investments. Financial gain for the employee is not the only criterion of a successful plan however. There may be other advantages, less tangible but nevertheless real which operate for success. An employees' stock purchase plan in the last analysis can only be judged as a part of the general policy of the company whether it be viewed by the employee or employer. It may supply the last stone in a structure of good will and cooperation or it may be an isolated and uncoordinated experiment without any particular value.

Extent of the Practice. There are at least 400 companies in the United States which have employee stock purchase plans. In these companies,

among which are many of the largest employing corporations of the country, it may be roughly estimated that there are at least 1,000,000 employee stockholders.

This paper is based on information obtained through a continuing study of financial relations other than wages between employer and employee. Analysis of more than 150 stock subscription plans, most of which are still active, forms the basis for the points here presented. The companies involved cover eighteen industries throughout the United States. The companies represented are large rather than small in number of employees. Small companies do not, as a rule, have stock available to any but their officers. The large majority of the active plans were originated after 1917. These companies afford a fairly accurate cross section of the entire employee stock ownership situation.

The present analysis touches upon those aspects which are of particular interest to employers. There are several phases which have not yet been adequately explored. Among these are the effect on the total income of the employee, the extent of influence of such plans on thrift and the degree to which labor turnover is reduced, the relative number of eligible employees who participate, and the relationships which employee stock ownership plans have with pensions, group insurance and relief benefit plans.

Stock subscription plans present so many and such wide variations in their provisions that it is difficult to segregate them into clearly defined groups. For convenience they are here grouped according to (1) structural forms, and (2) forms of financial aid furnished by the company.

Structural Forms. The most common structural forms are:

1. Convertible savings plans, in which the funds deposited by employees by methods similar to those of ordinary savings plans are later employed for the purchase of stock.

2. Plans under which employees subscribe to consolidated funds, later receiving allotments of stock in accordance with their credits in the funds.

3. Plans under which employees complete their payments in one year or less.

4. Plans in which the payments are extended over periods greater than one year.

5. Plans based upon the principle of investment trusts.

Forms of Financial Aid. Financial aid rendered by employers takes the following principal forms:

1. Concession in price at which stock is sold to employees.

2. Direct contributions added to employees' subscriptions. These contributions usually are a certain percentage of the amount paid by employees.

3. Interest payment on savings later to be used in the purchase of stock.

4. Outright gifts of stock; also arrangements by which stock is paid for by dividends without any actual expenditure by the employee.

5. Additional dividends or bonuses to employee stockholders.

6. Arrangements under which employees who complete payments for stock are allowed to share in funds credited by the company to the account of employees who cancel their subscriptions.

7. Profit-sharing features. These are of great variety. Most of them are based upon the general principle of distributing fixed shares of company

profits among employee stockholders in proportion to their ownership of stock.

Forms in Use. The different structural forms and different forms of financial aid are not always mutually exclusive. A single plan may fall into more than one structural classification, or may include more than one type of financial aid.

Plans have been analyzed on the basis of the classifications given above in an effort to ascertain whether certain features are common to certain types of companies and the degree of popularity of the various methods. It is evident that the choice of one type of distribution or another has no apparent relation to the kind of business or the size of the company.

The weight of precedent is in favor of relatively long term subscriptions, sometimes combined with a convertible savings plan and sometimes with subscription to a common fund. Relatively few companies offer their employees an opportunity to invest either in a convertible savings fund or a consolidated fund out of which payments are made for stock later.

Methods by which companies furnish financial support to stock subscription plans are also difficult to classify, both because of the wide variety of these methods and because of the fact that sometimes the practice of a particular company is not clearly defined.

In so far as it is possible to distinguish prevailing practices, no one type of financial aid is generally in use. More companies pay a bonus or extra dividend, however, than give any other sort of assistance and fewer allow employee subscribers who withdraw before the maturity of the plan to share in the fund created by company contributions to subscribers.

Types of securities offered by companies having stock subscription plans range all the way from common stock to employees' stock in special investment trusts. Between these two extremes are found various kinds of preferred and debenture stock, some of them carrying voting rights, others without voting rights and not subject to transfer. The information with respect to voting rights of employees is insufficient to determine definitely the preference for voting or non-voting stock. It is our belief, however, that relatively few plans do not extend voting rights with stock.

Terms of subscription and payment show wide variation, being dependent partly upon the structural type of plan in effect, the class of security offered, the eligibility requirements, and the individual ideas of the management.

One of the most common variations concerns the periods during which subscriptions are received. Many companies hold the subscription books open for a limited period each year; others allow subscriptions to be made at any time or as soon as each individual employee becomes eligible.

With respect to eligibility a variety of provisions are also found. Of the plans analyzed almost one-half specifically throw the stock subscription open to all employees. Companies which limit eligibility, do so usually through a service requirement, one year's service being the most common with six months second in prevalence. A few plans prescribe service requirements of two years or even five years. Besides the limits to eligibility based upon length of service, there are occasionally to be found some special limitations

as, for example, when the stock is offered only to officers or to selected lists of employees.

Certain companies limit the proportion of earnings which an employee may invest through the stock subscription plan; but this is not customary.

An important variation concerns the method of payment. Most companies that offer stock to the rank and file of the working force permit payment through payroll deductions; a few prescribe this as the only method; while payroll deduction is the favorite plan, other methods of payment are frequently to be found. Payment in cash at the time the subscription is made is permitted by many companies; it is rarely if ever required. Several companies require that a certain percentage of the purchase price be paid in cash at the time of the subscription and that the rest be paid in instalments, sometimes secured by notes.

There are numerous methods of crediting interest, dividends or extra payments by the employer to the subscriber's account, thus hastening his payment or reducing the amount which he must pay in cash or have deducted from his earnings.

Extent of Participation. There is a limited number of companies for which data are available showing the extent to which their employees participate in stock purchase plans. Participation is defined as buying or holding stock. Two-thirds of these companies have had stock subscription plans for five years or more. In the majority of this limited group more than 30 per cent of their eligible employees are participants under their stock subscription plans. The combination of at least five years continued operation with this degree of participation indicates a considerable measure of success.

There is some reason to suppose that the employees of the smaller companies have responded more readily to stock offers than have those of large companies, although the samples are too small to warrant definite conclusions. All but one of the companies of less than 1,000 employees about which we have details report a participation of 30 per cent or more. One-half of the companies employing from 1,000 to 5,000 workers have participating groups of 30 per cent or more of the employees. On the other hand, out of the thirteen companies employing 5,000 or more workers within the scope of this study only four companies have general participation.

Benefits to Be Secured. The statements of many executives concerning company experience with employee stock ownership plans combined with our own analysis of plans furnish the basis for some fairly definite conclusions as to what stock purchase plans may and may not be expected to accomplish. In addition it is possible to determine in a measure the desirability of some provisions over others.

Some of the benefits of stock subscription plans which either have been secured actually or which possibly may be secured may be noted. Obviously the same advantages will not be secured by every company nor are the ends sought by all employers the same; neither is it true that the results are in all instances peculiar to the operation of stock subscription plans nor best obtained by them.

1. Stock subscription, by providing a means of saving and investing money, encourages thrift. This result may be secured most effectively when

the terms of the stock plan permit payment of subscriptions by instalments deducted from the subscriber's wage or salary. From the standpoint of the employer, the workman who saves his money, supports his family in comfort and maintains accumulated funds to tide him over periods of illness or other adversity, is likely to be more steady and more efficient than is the man who spends his money as fast as he earns it. It is true that there is a conceivable argument to the contrary, based upon the fact that an employee who has saved money has a greater element of economic endurance in the event of a strike or a lockout than one who lives from hand to mouth, but this argument is seldom advanced by liberal-minded employers. Another counter argument occasionally heard is that thrift on the part of the laboring population will reduce expenditures for commodities and services, and thus injure business. This contention loses weight through the obvious facts that accumulated savings will be spent sometime, and that business probably profits more when wage earners are able to spend moderately, through periods of prosperity and depression, than when their expenditures are lavish during business booms and meager in times of widespread unemployment.

The employee who has accumulated savings is thereby made more self-reliant financially. Neither the employer nor the community need be called on in times of unemployment or illness. If continued over a considerable period such savings will supplement and may conceivably supplant the industrial pension.

2. A stock plan, if it adds to the earnings of employees and helps convince them that the employer is interested in their prosperity, should strengthen the morale of the working forces.

3. There is a general belief that employee stock ownership reduces labor turnover. This opinion, while it is difficult to prove with tangible data, is probably well grounded in the experience of some companies. Certainly it is logical to suppose that the employee who either owns stock or is paying for it, and who is thereby the recipient of direct financial advantages, will be less likely to leave the service of the company for trivial or insufficient reasons than would the generality of employees who lacked these incentives.

4. Stock participation ought to have the effect of attracting and holding labor which ranks above the average in stability and responsibility. The worker who deliberately seeks employment with a company which has a stock subscription plan rather than with a company which has no plan of the kind, may fairly be expected to remain with the company and to do his work in such a way that he will not lose his job.

5. The workman who owns stock of the company by which he is employed has to that extent a financial interest in the business. This fact should logically be expected to improve efficiency and economy by making the employee realize that the gains and losses of the company are to some extent his own. While the experience of some companies appears to bear out this argument, too much dependence should not be placed upon the effects of employee stock participation as reflected in efficiency and economy in any particular company. The dividends paid to the average employee stockholder are likely to be so low that they make up only a small part of his total

income, and considerations affecting this small part are unlikely to weigh heavily against things which he considers of more importance.

6. Whether or not the individual employee stockholder considers himself enough of a partner in his employer's business to be vitally interested in its success or failure, there is no question that such an employee has definitely become a participant in a capitalistic enterprise. This fact may be expected to give him a more conservative point of view toward industry and society generally; certainly such a workman cannot consistently support communistic or other extremely radical ideas.

7. A stock subscription plan affords one medium for giving employees first-hand experience with investments. This advantage may, however, be lessened or even reversed if the plan is drawn up or administered in such a way that the employee's stock is not subject to normal economic conditions.

8. Employee stock ownership secures a wider distribution of company stock than would otherwise be possible, since ordinarily the number of employee stockholders is added to the total number of outside stockholders without reducing the latter. This wide distribution of stock may be of benefit to the employer by lessening price fluctuations and by making it more difficult for interests hostile to the existing management to secure control of the company.

9. Investment by workers in the securities of employing corporations is likely to draw upon sources of capital formerly not available for industry. This is important in view of the fact that high income surtaxes have driven much of the money of large investors out of the industrial field.

10. One of the most important economic developments of recent years is the trend toward popular ownership of industry through wide diffusion of securities. It is generally believed that this trend is desirable and that it is having a stabilizing effect upon industry. Employee stock ownership serves as an aid to this general trend and therefore works to the advantage of industry in general.

Reasons for Lack of Success. There are undoubtedly companies in which none of the foregoing benefits would be obtained from an employee stock subscription offer. The following are some of the reasons which militate against the success of stock plans:

1. The possible gain to the employer through employee stock participation may not be sufficient to justify the cost of a particular form of stock subscription plan or of any such plan.

2. In some companies there is no practicable way of securing stock for distribution to employees. The supply of floating stock in the market may be limited or held at prices which make its purchase uneconomical; nor is every company in a position to issue new stock to be used in a subscription plan.

3. Certain companies have no security that is sufficiently safe and stable to make it suitable for investment by the workingman. There may even be a moral wrong involved in encouraging wage earners to buy securities which either involve excessive risk or are subject to violent fluctuations in price.

4. The present owners of many companies prefer to have the stock closely held by a few individuals or families. If there is a sound reason for this

preference, it naturally negatives any arguments in favor of distributing the stock to the rank and file of employees.

5. The laborers of some companies shift so frequently that only a comparatively small number could benefit by a stock subscription plan. This condition applies particularly in most construction companies. To the extent that it cannot be overcome, it would seem to furnish a valid reason for offering stock, only to the nucleus of steady employees.

6. Some corporations have had stock subscription plans which have failed under circumstances which seem to make the renewal of the experiment unwise. It is probable that on this account some companies ought not to promote stock subscription by employees, at least until after a considerable lapse of time. This is a point which needs to be decided by management on the basis of actual conditions.

Emphasis on Security. The Employee Investment Trust. Security is a fundamental need in employee investments. By virtue of their usually limited resources, employees can ill afford to take chances which may result in loss to them. Speculative investment is all right for those who can stand losses if incurred, but people in moderate circumstances do better as a rule by adhering to conservative saving programs. Thus employee stock ownership is by its very nature an institution devoted to thrift and savings purposes, although it has sometimes unfortunately departed from these objectives.

For several years the importance of safety in employee stock holdings has been stressed by industrialists and outside observers. This is attested by the large number of plans which provide either preferred stock or special employees stock well secured and by the various bonuses which extend the margin of security for the sums paid by employees. Because of his key position in the origin and administration of an employees investment plan, the responsibility for the ultimate outcome rests squarely on the employer. Since 1927 especially, the emphasis placed upon safety of employees investments has brought into being a new type of employees' security, namely, certificates or shares of stock of investment trusts created for employees of particular companies. This type, represented by the plan of the Dodge Manufacturing Company and the General Electric Securities Corporation, applies to employees' investments the principle of diversification which characterizes the investment trust development. This kind of plan has considerable promise, where the practical difficulties can be overcome, as a means of meeting the situation in companies whose stock, common or preferred, may be unusually speculative in character. It is also probable that a greater appreciation in investment values would result through an investment trust skillfully managed than through preferred stock of the employees' own companies.

Employee stock ownership is entering upon its second decade as a widespread movement. Many of the early plans weathered the 1921 deflation, while others subsequently formed have been built upon the experiences of their predecessors. The second test period began with the fall of stock prices in October, 1929, and will continue until the upward swing of the securities market has gotten well under way.

It was inevitable that employees under the wide variety of plans have had both fortunate and unfortunate experiences. Some have sold their holdings at a profitable figure during the rise in stock prices; others have unloaded, voluntarily or through force of circumstances, on the downward swing at substantial losses. These urges to sell usually grow out of the price fluctuations to the disregard of actual earnings of the stock, which may still justify the price originally paid. It might easily have occurred as a result of the recent misfortunes to many employees who held stocks of their own companies that the entire movement had come under disrepute. Notwithstanding, however, the substantial losses in some cases and the varied experience, the questions raised by critical observers are not directed at the continued existence and extension of the movement but rather at the manner of its continuance. Few now doubt the positive net advantages which have prevailed, but many have suspicions that adequate protection has not yet been taken against the element of risk.

Type of Stock to Be Offered. In the last analysis the determination of the type of stock to be offered to employees depends largely upon the circumstances of the particular company. A few generalizations, however, may be advanced with some conviction.

Participation in control and in the profits and losses of the business ordinarily can be secured to the fullest extent through the possession of common stock. Under the customary form of corporate organization this stock carries voting rights and its dividends are neither limited nor guaranteed. The holding of voting common stock makes the employee an actual partner in the ownership of the business and entitles him to a pro rata share in its gains and losses to the extent of his holdings. It gives him a personal part even though of limited influence in the control of the company and the selection of the management. The importance of the last mentioned consideration is largely psychological, since in the typical large corporation it seems unlikely that employee stockholders at any time in the near future will be able to exercise any real control over management; and since, moreover, with the stock widely distributed the management is to a considerable extent self-perpetuating and independent of scattered shareholders whether they be employees or outsiders. It is true, however, that the voting privilege, if it be regarded as important, may also accompany some preferred stocks.

Against the advantage of common stock distribution there must be set up some actual or potential disadvantages. First and of vital importance among these unfavorable factors is the instability of many common stocks. Both the price and the dividend rate may vary widely. Even more serious than instability of price is the risk which exists in some companies that the common stock will permanently lose a large part of its value or even become worthless as a result of bankruptcy or other business vicissitudes. The importance of a stable investment cannot be too heavily stressed.

No reasonable doubt exists that employees are more inclined to speculate with common stocks than with preferred stocks. The usual wide fluctuations of the former place temptations to sell before the holder when he sees a good profit. Selling on the way up, he has been known to regret his sales, buy in again near the top for a further rise and eventually see his stock go down

below his original purchase price. Again it takes a courageous employee to hold his stock through the bottom swing of the price cycle. All too frequently he loses heart and sells when he sees his values slipping rapidly away without waiting for his stock to come back to a reasonable price level.

Between the advantages and disadvantages of common stock as an offering to employees, the decision should be made largely on the basis of actual conditions. Common stock is widely regarded as a satisfactory security, provided its stability of value and earning power and its freedom from risk make it in a particular company the kind of a share that can be offered to workmen with reasonable assurance of safety. However, comparatively few companies in the United States have common stock which fulfills these requirements.

Many corporations, the common stock of which is unsuitable for subscription by employees, have preferred stock which may be offered without hesitation. Preferred stock as an employee's investment has definite advantages. In general its dividends are fixed and guaranteed, and thus the element of investment is emphasized and the element of speculation reduced. On the other hand, ownership of preferred stock does not ordinarily afford the employee as great a degree of participation in the enterprise as does the holding of common stock. His risks and his opportunities for profit are both reduced. Customarily he has no vote and thus exercises no control, even theoretically, over the management. The last named disadvantage, however, does not exist in all companies; sometimes the preferred stock has voting rights equal to those of the common stock.

In deciding between common and preferred stock the advantages and disadvantages of each should be balanced carefully. Sometimes the decision will be influenced by the purposes of the employer in initiating a stock subscription plan. If his desire is primarily to interest the employees in the business and to cause them to feel that its prosperity or misfortune is their own, he will naturally lean toward the selling of common stock. On the other hand, if he is influenced in the main by the desire to encourage thrift, he is likely to favor preferred stock and be willing to give up the greater interest presumably aroused by the ownership of common. The decision may also be influenced in part by the type of employees to whom the stock is sold; that is, whether they are wage earners or supervisors, Americans or foreigners, skilled or unskilled.

Instead of the regular issues of common and preferred stock, some companies have issued special stocks solely for distribution to employees. Sometimes these stocks are little more than certificates entitling the holder to shares of the company earnings. It is common to make these special employees' stocks non-transferable or to require that they be sold back to the company or exchanged for different securities if the holder leaves the service. Of special employees' stock it may in general be stated that the issuance of such securities instead of regular stock requires affirmative justification, since ordinarily there is a distinct advantage in giving the employee to understand that the shares he owns are just like those of the other common or preferred stockholders.

Main Features of Structural Plans. Various considerations must be taken into account in actually formulating a stock subscription plan.

1. *Convertible Savings Plan.* Plans of this type usually lay emphasis upon the savings features. The employee is encouraged to subscribe to savings certificates or other evidences of investment and these certificates later are transferable into stock of the company, sometimes with alternative investments for those who prefer them. A plan of this kind may readily be used to encourage home ownership or other forms of economic independence in addition to stock subscription. It has the advantage of furnishing a convenient means of inducing the wage earner to save his money without the appearance of committing himself to the purchase of stock or to a long term subscription. On the other hand, a convertible savings plan may lack some of the advantages of a direct stock subscription and may therefore be less effective in enlisting the interest of the employees in the success of the company. Much depends upon the character of the administration of the fund. The trustees or other administrators need to be selected with care, in order that the employees' money may both be kept safe and be handled wisely. This applies equally to a plan providing for a consolidated fund.

2. *Subscription to Consolidated Fund.* A fund administered by trustees and used for the purchase of stock for distribution to employee subscribers in proportion to their credits has the advantage of easy control and comparatively simple bookkeeping. As worked out in some companies a fund of this kind has an additional advantage in that it can be invested in stock at times of low prices or loaned temporarily on interest when this seems the most profitable course. From the standpoint of the employee there is little difference between subscription to a combined fund and direct payment for stock on the installment plan; in fact, it is likely that the average employee subscriber does not know the difference.

3. *Payments during One Year or Less.* Direct purchase of stock with the payments extended over periods of one year or less has been a method employed by relatively few companies. There is no fundamental difference between this method and that of subscriptions extended over longer periods. The short time subscriptions are somewhat easier to control and involve less danger of wide fluctuation in stock prices during the time of payment. It may, however, contain a greater element of encouraging speculation than the long term plan, since the subscriber secures control of his shares in a comparatively brief time. From the standpoint of the employee the short term has the advantage that it does not commit him to fixed payments over a long period of years.

4. *Long-term Subscription Payments.* Stock subscription payments extended over relatively long periods—from two to five years are common subscription terms—have the advantage that they are likely to induce fixed habits of thrift and saving. A workman who subscribes every payday for three or five years is less likely to give up his habits of thrift than one who completes his payments in a few months or a year. Likewise it is probable that the employee who receives a fair sized block of stock at the expiration of a considerable period is less likely to sell it than the one who gets a smaller amount after a short time. Then, too, the dividends on the larger holding

are sufficient to be appreciated, whereas the income from stock paid for in a year or less is likely to be so small that the subscriber will consider it of little account. This type of plan is open to the possible objection that it commits the employee to a fixed schedule of payments during a long period, in the course of which his economic conditions may change. This objection can be neutralized by providing easy terms of alteration, withdrawal or termination of subscriptions.

5. *Employees' Investment Trusts.* The fifth type of plan may have any one of the methods of payment found in the usual employee stock plans. Its principal characteristic is the diversification of investments as compared with the security of the employees' own company. An investment trust for the exclusive participation of employees of the company which sets up the plan provides a medium for the purchase and sale of securities of other companies. Such a trust can be no sounder than its management but when wisely administered certain weaknesses inherent in the ordinary types of plans may be avoided. The first of these defects, as already indicated, is that of having the employees' "eggs all in one basket."

The second evil grows out of the fact that some employers use these plans as unwarranted pressure upon their employees to bind them to the company when wages and other working conditions might influence them to seek positions elsewhere. This evil may be avoided in fact by the maintenance of wage levels and working conditions equal to or better than the prevailing standards of the particular industry and community. However, it is difficult to avoid the appearance of undue influence and paternalism if a bonus is granted with a string on it, namely, that they remain with the company. If, on the other hand, the company recognizes a real value in having employees who save money there may possibly be sound reason for it to compensate the employee who saves accordingly through a bonus which places a premium on saving. Such a bonus logically is based on the amount invested under the plan and not on length of service or on earnings from his job.

It is contended that the following principles governing employees' investment trusts will go far to offset the weaknesses above mentioned:

a. The diversification of securities purchased by employees' investments and the management of these funds in accordance with sound financial practice. This involves complete independence of employees' funds from the funds of the company in which they work and the management of investments by an outside financial institution engaged by the board and responsible to the employees investment corporation.

b. The company or corporation set up to handle these investments shall virtually be a cooperative enterprise of the employee investors themselves. In this connection it is important, however, that where the name of the employing company is used or otherwise involved the officers of such company must protect its reputation before the public. Furthermore, there exists a certain moral responsibility upon the creators of a plan even though it be a cooperative one, for its sound administration.

The five structural types just outlined are not of necessity mutually exclusive, since subscriptions to convertible savings plans, to consolidated

funds, or to investment trusts may be by means of either long or short term payments.

Administration of Plans. Eligibility. A service requirement for eligibility to subscribe for stock is desirable, since in most companies the bulk of the labor turnover is among the very short term employees, and by excluding these men much bookkeeping and many cancellations may be avoided. On the other hand, there is ordinarily no occasion for a particularly long service requirement. A stock plan open to employees after one year's service, or perhaps even after six months, will not be encumbered ordinarily with subscriptions of "floaters."

Some companies limit their stock subscription plans to certain types of employees. For example, a company may exclude all except the rank and file of the workmen, or, on the other hand, it may exclude all except officials. These distinctions need to be justified by the conditions or purposes of the specific company or by the nature of the security offered; they are not demanded by any facts or theories applicable to stock plans in general.

Limits to Subscriptions. It is probably desirable to limit the current investments of employees to a reasonable percentage of their earnings between 15 and 25 per cent. It is true that the average workman is inclined to save too little rather than too much, but the occasional miser ought not to be encouraged to lay aside a proportion of his income great enough to cut down unduly his expenditures for necessities and comforts. Even if it were wise for an employee to save one-third or one-half of his income, he ought not to put this amount into a single security.

Some companies set an absolute limit on the amount of stock to which any employee, regardless of his earnings, may subscribe. There appears no general justification for this practice, but it may be advisable in a particular company (1) if the amount of stock available is limited; (2) if the company gives liberal financial aid and it is thought that there is no occasion to furnish this aid in unreasonable amounts; or, (3) if the lack of an absolute maximum would give the official class too great a proportionate participation in the plan.

Methods of Payment. Experience and reason both give approval to the system of payment by deductions from wages or salaries. This "painless" method of saving money generally is satisfactory to the employees themselves and saves much bookkeeping and collecting by the employer. Also, it is a strong incentive to thrift through systematic saving. If a man wants to pay his instalments in cash or even settle his account in full, it is difficult, however, to justify a refusal, although in some cases the privilege of paying up accounts and securing possession of stock before the expiration of the regular term has encouraged speculation, since employees have seen the chance to profit by raising the money to buy their stock outright and then selling it in the market. When this danger exists the employer may fairly require that payment be made only by the regular instalment system.

Cash or Stock Withdrawal. The working man unaccustomed to stock ownership or investment is likely to be suspicious of a plan which seems to tie up his money for a period which he cannot control. In recognition of this fact most companies in initiating stock subscription plans make liberal provision for withdrawal. Under some plans the subscriber is allowed to withdraw

his money with interest at any time before he has actually received stock certificates; in others the employer reserves the right to furnish stock or cash at his option. The latter alternative serves to prevent possible financial embarrassment to the company if many subscribers withdraw at one time.

Although a great deal has been said about the use of employee stock ownership as an agency for holding the employee to his job in case of strike against the company or in face of low wages or unsatisfactory working conditions, a thorough analysis of the improvement fails to support these criticisms. If there have been instances where undue pressure was placed upon the employee through the instrument of such plans they are but unfortunate exceptions to the general practice. Even the most abstruse employer cannot fail to foresee that the use of the plan as a threat over employees would result in the loss of constructive values which lead toward financial independence through thrift. It is therefore generally regarded as desirable to allow liberal and easy provisions for withdrawal by the employee from the plan.

Guarantees against Loss. Certain companies not only permit the cancelling of subscriptions before the term of payment is completed, but attempt to guarantee employee stockholders against loss even after they have received their shares. In attempting this kind of a guarantee a company may agree to take back the stock at par or to buy it at any time at the price for which the employee purchased it. A guarantee of this kind would seem to be unwise in at least two respects: (1) it is an attempt to bind a future board of directors perhaps illegally to a predetermined policy; and (2) it involves the danger of teaching the workmen something about economics which is not true: *viz.*, that a man can be a partner in a business enterprise without running any of the risks of the business.

Sale or Transfer of Stock. It is generally best to allow the employee stockholder to sell his stock freely in the market after he has paid for and received it. Some companies limit this privilege either by issuing non-transferable certificates or by binding the employee to offer the stock to the company before he sells it to an outsider. These limitations of the privilege of sale may be justified only if warranted by peculiar conditions. In the absence of this justification, there seems to be no excuse for selling the employee stock "with a string to it." It must be admitted, however, that one of the purposes of most employers who sell stock to their workmen is to secure the advantages of a permanent body of employee stockholders.

Extra Payments for Retaining Ownership. The chief value of stock purchase lies in continued ownership. However, the returns from securities in which the element of safety is high are too low to be particularly attractive to the workingman; there is danger that he will sell his shares as soon as they get into his hands and attempt to draw larger returns by reinvestment. This is particularly true in the case of some companies which, although stable and prosperous, make a practice of paying unusually low dividends.

Several companies have solved this problem with greater or less degree of success by paying special bonuses or extra dividends to employees who remain in the service and retain their shares. Sometimes these extra payments are limited to a fixed term of years; at other times they are for an indefinite period or until revoked by the management. These extra payments

are justified as they secure the desired result of inducing employees to hold their stock.

In this connection, the company initiating a stock subscription plan ought to consider how, if at all, the financial incentive should be *divided between aid in purchasing and special inducements for holding stock*. A company might to some extent defeat its own purpose if, through liberal aid in purchasing, it induced large numbers of its employees to subscribe for stock, and if then on account of low dividends most of these same employees should sell their stock as soon as they received it. In such a situation the company might find that it had spent its money without securing all the advantages which it desired, and which might have been gained by a division of financial aid between contributions toward purchase and extra payments after the stock had been allotted.

Company contributions toward stock subscription plans usually have been made through one or more of the following methods:

Concession in Price. Concessions which are given range all the way from one or two points to a price so low as to constitute practically a gift of the stock. Moderate price concessions do two things: (1) they take the place of a direct contribution toward the employee's savings, and (2) they protect the subscriber to a degree against declines in the price of the stock. The latter result is important, particularly if the stock offered is subject to considerable variations in the market.

Direct Contributions. Some companies pay a direct money contribution into employees' stock purchasing fund. Occasionally a stock subscription plan provides for direct contributions and concessions in price at the same time. The two methods are similar in principle. Conditions in a particular company may serve as the determining factor in a choice between them. Care should be taken that neither the amount of company assistance nor the manner in which it is offered warrant the charge of paternalism.

Interest on Savings. If stock ownership and participation in dividends are withheld until payment is completed, the employee should be paid reasonable interest on the balance in his account. This practice is almost universal, particularly in plans of the convertible savings type. The interest upon balances may be one of the most effective incentives for continuing participation.

Gifts of Stock. A few companies have plans in which to all intents and purposes the stock is given to the employee without payment. Plans of this kind are exceptional and require some specific justification. They have not been considered extensively in this paper.

Participation in "Jack-pot." In the operation of any stock subscription plan there will be some cancellations and withdrawals. When the plan is financed in part by direct contribution from the company, the question arises as to what shall be done with the payments which have been made for the account of those subscribers who do not continue until the maturity of the plan. Some companies divide this indeterminate amount among the survivors; others withdraw it from the fund if there is one. There is no exclusive argument for either method. If subscribers who cancel their accounts do not participate in the money contributed by the company it is difficult to see why the employer is required to give this same money to other subscribers in addition to that which they are entitled. The privilege of participating in the

jack-pot is in fact an increase in the liberality of the stock subscription plan and is to be justified, as are other liberal features, on the basis of the beneficial results secured by the company. It is true that the argument sometimes is heard that if the employer recovers the contributions made for the accounts of subscribers who withdraw, he may be tempted to discharge employees and thus save money. In the case of most corporations this argument is somewhat far-fetched, and it could be counterbalanced by the contention, directly opposite and equally far-fetched, that if the jack-pot is divided among the survivors, foremen, and other participants in the stock plan might scheme to get their fellow employees forced out of employment in order that more might be left in the fund which they would share.

Methods of Sale. Otherwise inexplicable differences in the degree of success attained by stock subscription plans often may be accounted for by the methods by which the stock is sold. A stock subscription plan, particularly a new one, is unlikely to meet with a widespread response unless it is presented to the employees intelligently and with some degree of enthusiasm by the management. On the other hand, there is danger that officials may promote a stock subscription plan with a degree of insistence that approaches coercion. This type of selling is likely to create a bad impression and may even be ethically wrong if its effect is to induce employees to subscribe unwillingly or to a greater extent than they can afford. In initiating a plan of stock subscription much attention should be given to the selling methods that are to be adopted and to the explaining of these selling methods to the officials who are in direct contact with the working force.

In the final analysis the sale of company securities to employees may succeed or fail for reasons entirely beyond the conditions of the plan itself. The confidence of the employees in the integrity of the management may be so deep seated and the morale so high that any plan for the sale of stock to employees would meet with marked success no matter what its defects. On the other hand, the most ideal plan will be doomed to failure if launched in an atmosphere of distrust and low employee morale.

SAVINGS AND THRIFT PLANS FOR EMPLOYEES

BY H. GILBERT FRANCKE, *Consultant on Labor Relations*

By far the largest part of the literature on employee thrift and savings consists of detailed descriptions of plans that are in force in individual plants, how they are operated, what per cent of the employees have taken advantage of the plan, how the plan has grown from a modest number of dollars to a financial giant and what many advantages can be found in these plans. These articles have, quite naturally, neglected to put much emphasis on the negative side of the schemes and it has been left to the imagination of the reader to determine for himself what, if any, the disadvantages might be. Surprisingly little has been written on the general subject and, therefore, an attempt will be made in this article to list the principles which are back of any thrift plan, to point out some of the pitfalls that attend the use of such

plans and to enumerate the different kinds of plans that are adaptable to industry today.

Security of Funds the First Essential. It is very obvious that the first principle of any thrift plan must be the security of the funds collected from employees. In the many different types of thrift plans the security varies from the often quite hazardous plan of selling a single common stock to employees at market price, or slightly under, to a safe and sane pay roll deduction plan where the funds are deposited in savings banks to the credit of the individual employees.

In determining whether a savings plan has sufficient security, other factors than the earnings of the company and the fluctuations of the market price of the stock must be considered. In the first place, the average employee is wholly dependent for his livelihood on his job, in other words, he is already carrying, as far as he is concerned, a big risk in the enterprise in which he is engaged. Therefore, the question whether this risk should be increased by encouraging the employee to invest his funds in the same enterprise must be answered by an impartial review of the particular situation. In the second place, the need of security will vary with the financial standing of the employees for whom a savings plan is devised. If it is for managerial employees, who, presumably, have some of their funds invested in other enterprises and have a reasonable amount of life insurance other than term or group insurance, then the security of a savings plan takes on a different aspect than if the plan is primarily for employees who are making possibly their first venture in systematic savings.

Importance of Simplicity of Plan. Next in importance to security comes simplicity of any savings plan. There is no question but that in the minds of the average industrial worker a tremendous amount of mystery surrounds all financial matters. Balance sheets, bond issues, surplus, stocks, sinking funds, depreciation, etc., are all names to conjure with and to convey to many persons the thought of juggled figures. Therefore, a straightforward and simple savings plan will be understood and appreciated, while an elaborate one, surrounded by magnificent legal terminology, will arouse suspicion on the part of the average employee.

Flexibility. Any savings plan must be adaptable to the many changing conditions that may confront the persons who are using it. A too rigid plan will work hardships on employees who, in good faith, undertake to save systematically but who encounter things beyond their control. Therefore, a plan must provide for easy withdrawal of funds, for intermittent payments and for cancellation of agreements to participate.

Convenience. Finally, a plan must be convenient for employees. One that puts the burden on the employees to make periodic payments to a treasurer, or through collectors in the plant, will not function as effectively as one that provides for pay roll deductions by the company. The comparatively small amount of work that must be done by the pay roll department is distinctly worth while in causing more widespread participation by the employees in any savings plan.

Types of Plans. There exists today, in actual practice in industry, a wide variety of employee savings plans and a brief description of these follows, but

no effort will be made to say which type is best adapted to a particular case as the purpose to be accomplished and local conditions must determine which one is to be adopted.

The simplest form of thrift plan is the one where the company merely acts as the collecting agent for one, or for a number, of savings banks by deducting specified amounts from the pay of those persons who so authorize the company through a signed order and deposits the money to the account of the individuals who take part in the plan. Thereupon, the responsibility of the company ceases and the employee is free to do what he desires with his savings bank account.

A variation of the scheme is to replace pay roll deductions by banking machines, which sell stamps that are redeemable at a specified bank for a savings account. Although these machines relieve a company of all of the responsibility they do not insure the same regularity of saving that the pay roll deduction plan provides.

Next comes a similar plan where the money collected from the pay roll is used for two purposes: buying savings bank life insurance in the states where the law permits and building up a savings account. The added feature of life insurance supplies one of the greatest needs of the average employee, namely, protection for his family while he is also saving and does so at a minimum of cost.

The sale of common or preferred stocks to employees on an easy payment plan at less than market price, or with a premium after a certain number of years, is one of the most common forms of thrift plans. Some of the attendant hazards have already been mentioned and deserve careful consideration. These plans are often inaugurated as thrift plans with the best of intentions, but are received by employees as a "get-rich-quick" proposition. In other words, employees who subscribe to some of these plans are thinking more of the possibility of increased stock market values of their purchase than they are of systematic savings. On the other hand, there are unquestionably great advantages of having large numbers of employees who are stockholders and who are, therefore, more vitally interested in the success of an enterprise. This may be manifested in a number of directions—decreased labor turnover, improvement in quality of output, reductions in manufacturing costs, savings in waste, and improved morale.

A natural development of plans of selling individual stocks to employees has been that of selling shares in investment trusts with the advantage of spreading the risk for those who can least afford the risk of an individual stock and with the disadvantage of the responsibility of administering the trust. But the advantage far outweighs the disadvantage in concerns that are sufficiently large to provide the best possible financial administration.

The term profit sharing has covered a multitude of things, some of which might be called sins. It is certain, however, that it should not be classed under thrift plans as it is either a special reward for successful efforts or an integral part of a method of financial remuneration. In like manner "economy dividends" the merits and demerits of which are not to be discussed here, do not come under the subject of this article but rather belong under a discussion of bonus plans as distinct from thrift plans.

The credit union provides one of the best devices for encouraging thrift among employees as evidenced by the adoption of credit union laws in thirty-three states of the Union and by the tremendous accumulation of funds in credit unions. It provides for systematic savings in varying amounts so that the lowest paid and the highest paid employee can save at a rate that fits his particular situation. It is supervised by competent authorities other than the employer and, therefore, does not in any way complicate the "employee-employer" relationship. It is sufficiently flexible to permit of activities that will cover the financial problems of the average employee, such as savings for home building, for making large payments on coal, taxes, education, etc., and for emergencies such as serious illness, that often financially cripple an employee, who is unprepared to meet them. In addition to providing savings for these and similar purposes, it establishes the credit of persons who are unable to get credit from other sources without paying exorbitant rates of interest. It does not, however, provide the privacy for loans desired by some employees. To a certain extent the voluntary building and loan association gives some of the advantages of the credit union and both are an extremely useful educational device for teaching some of the fundamentals of financial matters to employees who must take part in their administration and, through them, to the rank and file of the workers.

Although they do not, strictly speaking, fall into the category of savings plans, a number of closely related subjects should be briefly mentioned, both because they divert some of the funds of an employee from the channels of saving and because they take care of some of the elements in a well thought out savings program. For example, group life insurance paid for in some part by the employees is not saving as there is no cash value to the individual policy, but group life insurance does supply one of the first elements of saving, namely, protection.

Employee participation in mutual benefit associations to cover loss of pay from sickness and pension systems, both contributory and non-contributory, play their part in decreasing the hazards to employees and unemployment funds, although quite in their infancy in American industry, will continue to grow and will aid in solving the greatest problem that confronts employees today.

Results of Thrift Plans. What then are the general results either to employee or employer of a sound saving and thrift plan—results, all of which will not be found in any one plan, but which do appear in a general survey of a number of plans?

In the first place, definite channels for saving will greatly increase the number of persons who save and will include many persons who were absolutely ignorant of their ability to save. This, in turn, will lead to a sense of accomplishment which can only react to make the saver a more competent person.

Systematic saving means systematic spending and this can only be accomplished by budgeting and well ordered finances mean better home environment and furnishings.

Home building and home owning, a feature that develops a backbone of valuable employees to any organization, is greatly encouraged by any thrift plan that deals in real estate mortgages.

Educational opportunities for the individuals who save, or for members of their families, are greatly increased by thrift plans.

Credit unions develop the credit of the mass of people on the basis of character and accomplishment as well as on the basis of financial worth.

Thrift plans decrease the field for the loan shark who can exact the pound of flesh from the unfortunate individual who, through pride or through ignorance, is unable to obtain emergency funds elsewhere.

Wage attachments, a nuisance to an employer and often a tragedy to the employee, are reduced through savings and thrift plans.

In conclusion, any thrift plan that meets the major requirements of soundness, simplicity, flexibility, and convenience, will be beneficial to both employer and employee and, therefore, beneficial to society in general as well.

THE CREDIT UNION ITS PRESENT AND POTENTIAL SERVICE TO INDUSTRY

By ROY F. BERGENGREN, *Executive Secretary, Credit Union National Extension Bureau*

The oldest Massachusetts credit union was established in 1911. The Massachusetts credit union law was enacted in 1909 and thirty-four other states have now enacted similar laws. Back of the Massachusetts experience is the history of successful credit union operation in Quebec, dating from 1900, and back of that a very substantial development in Europe, dating from the early experimentation by Raiffeisen in Germany in 1848. There are now over fifty thousand credit unions in Germany alone, and the spread of the credit union is world wide.

What Is a Credit Union? A credit union is a cooperative society, organized within, and limited in its operations to, a specific group of people operating under the supervision of the state banking department (from which department it gets its permit to operate) and self-managed, serving two purposes: (1) providing its members with an easy and convenient system for saving money, supplying thereby the capital which enables them (2) with their own money and under their own management to take care of their own short-term credit problems at legitimate rates of interest, loans being made only to members of the group and at fair rates, with the resulting earnings reverting to the members of the group as dividends on their savings.

How Is a Credit Union Organized? Let us assume that there is interest in credit union organization at the Black and White Company and that the company employs fifty or more people.

There are successful credit unions in groups varying in number from fifty to many thousand.

There are four steps in the organization process: (1) the development of an attitude of friendly acquiescence on the part of the executives. The credit union must be managed by the employees, but the executives must be sufficiently favorable to credit union organization to adopt a friendly and willing attitude towards it. (2) The development of interest and a willingness to go ahead on the part of a representative (but not necessarily large)

cross-section of the employees, and their petition to the state supervisory department for a permit to operate. Every credit union starts small and develops slowly at first in order to give the directors and committee members opportunity to master the routine before there is much of it. I organized a credit union (with present assets of over \$500,000) five years ago with a dozen members and \$18—a typical beginning. (3) The decision of the state department to grant the charter. (4) If the charter is granted, the organization meeting, adoption of by-laws and the beginning.

Requirement of Members. To become a member of a credit union I must first be a member of the specific group within which it is organized. I must then agree to save at least \$5 (one share) by paying cash for it or at the rate of 25 cents a week. If I can save 50 cents a week I subscribe to two shares, paying in 25 cents a week on each share; if \$1 a week, to four shares, etc. The member who can save the least is welcome, as is the member who can save the most, the theory being that by the time my first share or shares are paid for I will have acquired the habit of saving and that I will go right on thereafter saving automatically and indefinitely. Many Massachusetts credit union members now have in their credit union individual savings to the Massachusetts total maximum—\$4,000.

As a thrift plan the credit union operates for the maximum convenience of the member. Two claims are made for it, both of which are vital tests for any thrift plan and have been substantiated by much practice:—it is claimed that the credit union will induce a larger proportion of those eligible to membership to save than will any other system. Some credit unions have a 100 per cent membership and 70 to 80 per cent is usual and average. Further in a credit union a saver will average greater individual saving.

Problem of Small Loans. We have in the United States a very definite and difficult problem which results from the fact that the average worker and small farmer is without normal credit facilities available for his use in time of credit necessity, a problem which is much aggravated by the further fact that the modern plan of mass production and extended merchandise credit makes for money credit necessity. The Uniform Small Loans Law, now operative in many states, permits the private lender, who operates under regulation, to charge 42 per cent on loans of \$300 and less, the justification for the law being the unhappy fact that the private lender, operating without restriction and regulation, charges a rate so high as to make 42 per cent seem low by comparison. A recent survey by the Twentieth Century Fund indicates that the unlicensed lender—the simon-pure loan shark—still is the largest factor in the small loans business, doing business at rates higher than 42 per cent to a total in excess of \$750,000,000 a year.

The *Credit Union National Extension Bureau* is a non-profit-making organization, financed by Edward A. Filene, and carries on its work as a completely disinterested public service. Its office is located at 5 Park Square, Boston, Massachusetts. Its staff includes field secretaries in all of the thirty-five states with credit union laws. The Bureau will supply complete information on request and assist by personal contact any executives and employee groups within any industrial units, located in the states with such laws, to make use of them.

CHAPTER X

SERVICES FOR EMPLOYEES

SOCIAL, RECREATIONAL, AND ATHLETIC ACTIVITIES

By BERENICE P. TWITCHELL, *Personnel Manager, Pilgrim Laundry, Inc.*

Purpose. Any phase of personnel work, which helps to create a more friendly feeling between management and employees, cannot help but be of value to the organization. This need not mean friendly, as opposed to unfriendly, but that which increases better acquaintance and, through this, better understanding. This, while there are many others, is perhaps the best reason for promoting social activities in industry.

Everyone has had the experience of becoming better acquainted with an employee through some special incident, whether it be feast or famine, fire, or flood. After such an incident, one can never drop back to the old footing—a deeper association has been established. This is what we strive to accomplish with our social program, reaching large numbers rather than a few individuals. The creation of an atmosphere in which employees feel that they are looked upon as human beings, each with his own problems, interests and desires, does not necessarily involve a paternalistic attitude on the part of the management, nor does it have any connection with slack discipline. That such an atmosphere is a business asset to a company, of the highest order, has been demonstrated wherever it has been secured. A girl in a large organization said, "I like my work and am satisfied with my salary but I never feel that anyone cares about me personally or cares whether I am happy or not." It is not my thought that social activities alone will produce the good morale which is dependent upon more basic matters but it is obvious that a social program gives added opportunities and opportunities of a varying kind for cultivating the right atmosphere in a plant.

How Best to Function. There is no set social program which can be generally adopted. Each industry is a different problem, and what would be suitable for one would be all wrong for another. The best procedure is to use a committee whether it be "house" or "factory" or other title. If there is no such committee, to form one would be the first step. Success depends on ability to speak the other person's language, and this committee will be able to keep in touch with the wishes of the larger body. With such a committee in charge of the social program, management need give advice and assistance only when it is requested or obviously acceptable. This puts the responsibility where it belongs, on the group which is concerned. Employees are much less likely to take genuine and sustained interest in something

which they feel is being handed out to them. Moreover this method insures against the very unfortunate situation in which employees feel under compulsion to participate in activities because these have been planned by management.

It should also be left to the employees to work out the details of their activities. They should, however, feel assured of the interest of the management, and this may be shown in a variety of ways. To illustrate, the baseball team may only need transportation to and from the field, or it may need help with buying uniforms; or it may need only the encouragement which will come if certain offices in the athletic association are held by management or from management attendance at the games or a dinner to the team to wind up the season.

Some of the Media. Social, recreational, and athletic activities may be listed as follows:

Social	Recreational	Athletics
Clubs.	Roller skating.	Baseball.
Dances.	Tap dancing classes.	Swimming.
Holiday parties.	Deck tennis.	Basketball.
Salesmen's suppers.	Rowing.	Bowling.
Dinners.	Musical clubs.	
Outings.	Sewing classes.	
Camps.		
Theatre parties.		
Dramatics.		

There are doubtless many other things which could be used to advantage, but this is a list of forms in practical use in many firms. These items could be classified differently but those of the first list lend themselves best to social and friendly contacts. The activities of the second group benefit through teaching something. When an activity is beyond the reach of an individual and he is helped to attain it, he grows mentally through the satisfaction of doing the thing he felt was beyond him. The activities of the third kind benefit the individual physically but what is more important, they carry into the entire organization the spirit and enthusiasm aroused by outside competition.

What Shall We Choose? This is perhaps the most difficult part of a social program. We may see the benefits of all sorts of activities clearly but what shall we choose for our personnel. Some say, Help people to have a good time in their own way. That is good but we want also to help them to find variety and new interests. We can at least use common sense and we would not offer sewing classes to those who sit over a machine all day. Amateur theatricals are usually popular. I have seen this form of activity grow from a brief sketch given in a plant cafeteria to an evening performance before an audience numbering 1,000—and the latter was coached by an employee. In contrast I have seen a swimming class fade out of the picture either badly managed or the wrong activity.

A word more about the value of amateur theatricals. I have seen no other medium that has quite the same value. Some of the benefits are:

1. Some advertising value.
2. A large number can participate
 - a. Acting.
 - b. Ushers.
 - c. Stage management.
 - d. Transportation.
3. Discovery of leadership.
4. Discovery of talent.
5. Pride in organization.

The Christmas holidays are a good occasion for social contacts. It is not necessary to present gifts, but it is possible to promote the getting together of groups for friendly pleasures. Perhaps there is no happier medium than the Christmas party that welcomes those at home as well as those who are employed. It is a valuable contribution when parents or husband or wife also get the feeling of friendship for the company that is necessary for the best conduct of the business.

We can be pretty sure that the activity will succeed that has been requested and then worked out by a committee which finds out the real wishes of all concerned. A theater party at \$2.20 may be arranged arbitrarily and prove a failure and a 50-cent movie party, arranged by a committee, may be a great success. The committee party succeeds because they take the trouble to find out what price entertainment the group wants.

A travel club is another medium that promotes the object of "getting to know the other fellow" and is educational and satisfying. An interesting one in Scotland is conducted in a textile mill with the "shut-down" type of vacation. The club functions throughout the year and on this week of vacation goes to some part of Scotland for sightseeing. The personnel manager makes all arrangements and goes with the group. As this is not her vacation period it is clear that the management feel it is worth while to help these girls to have just the vacation they want most.

Why Several Activities? It is not a cause for immediate discouragement when only a few people take interest in an activity. The situation should be analyzed and evidence found as to whether the interest of the few is not strong enough to make it worth while. If only a small group profits that does not always mean it is the wrong activity. We may find it is the only thing that that particular type is drawn to. It is possible that the "single-activity" person does more for the organization in his comments both inside and out, than does the one of wider interests. We never know just what will be met with enthusiasm. Enough activities will serve a varied group and it is to our advantage to appeal to all types.

WHAT SHOULD BE PRINTED IN EMPLOYEE MAGAZINES?

By **STERLING PATTERSON**, *Editorial Director, Western Electric Company, Inc.*

A personnel periodical is any publication appearing at regular intervals, which is designed to be circulated among and interest mainly, the workers

in any given company. These publications may take various forms. They may be monthly magazines, weekly magazines, weekly newspapers, daily newspapers, semimonthly newspapers, mimeographed sheets, or even blotters. They may go to office workers, factory workers, or the sales force. As long as they have publication dates, the date when the employees may look for them to appear, we may consider them periodicals.

A summary of the basic purposes of such a periodical was made by the Western Electric News as follows:

1. A natural medium for the expression of our common interests and a complement to human contact with our fellow employees.
2. A means of telling us where the parts fit into the whole, and what becomes of the products we make.
3. A human interest undertaking because we readers are human beings with the usual human reactions.
4. A medium which must appeal to us chiefly through our three main interests—our jobs, our homes, our hobbies.

Labor Policy Important. A personnel magazine is essentially a part of a personnel program. It is one of the undertakings which a company may carry on in an effort to bring about mutual understanding and trust between management, workers and stockholders. Perhaps it is better to say between workers and investors, for those who are generally referred to as management are, with most of us, employees and certainly are workers.

If the relations between management, men, and investors are not friendly and the company publishing the periodical is honest, the magazine may help to bring about a friendly condition when employees are treated fairly and given the facts. Men as a whole draw the right conclusions. But this does not imply that an employees' magazine is a panacea for labor ills. It is only one means at the disposal of management which may be employed in working toward the goal of harmony.

One of the functions of a personnel magazine is to explain the interlocking interests of management, worker, and stockholder. When in addition to this explanation, arrangements are made so that the workers may easily become capitalists as well (through employee ownership of stock), fully half of the misunderstanding is done away with.

The Company's Motive. In the case of many personnel publications there would seem to be a lack of a definite policy. Indeed, at times we feel that some magazines are published perhaps because other companies have found them successful. Some papers look as if the job of editing were a part-time job of someone in the employee relations or advertising departments, often a person not equipped to be an editor; and consequently the publishing of the magazine may be a waste of money.

The Complexion of the Audience. The intelligence of the employee magazine audience is almost invariably underestimated. Personnel publications are likely to "write down" to their audiences. This unquestionably is a mistake. From the literary standpoint a personnel publication is like a newspaper. As one well-known New York newspaper editor phrased it,

"A newspaper is edited for the approximate mutt." So is a personnel periodical, but this does not mean that said mutt has not a native intelligence which will operate in perfectly normal fashion provided the vocabulary of the magazine is his vocabulary. If the audience includes a large number of people who do not speak English it is still quite likely that they will know everything that appears in the magazine; first, through pictures, and secondly, through their children who are going to school and can read the magazine when it is taken home. If the periodical does not have a family circulation a great opportunity is being missed.

The Editor and His Status. It is difficult to find the right kind of man, or woman, to edit a personnel publication. He should be an educated, broad-minded man with an interest in humanity. He should be trustworthy. He should have a pleasing personality. He should be a good journalist, should know the mechanics of his work, and should have artistic ability. He should be distinctly a part of the company, but at the same time he should be able to take an impersonal view of management, workers and stockholders and to make fair decisions with regard to them. He should be able to earn as much money in editing a personnel publication as he could earn in editing a magazine of general interest.

Perhaps more important than the man himself is his status. One editor who is doing an outstandingly good job, reports to the president of his company, has complete freedom as to what goes into the magazine and what stays out, is responsible for the magazine only to the president but sits in on all meetings of the department in charge of employee relations. The editor should report sufficiently high up the line to get a broad view of his company and the industry. He must be very close to the people who are handling relations with employees, but it is probably better for him not to be actively engaged in the administration of that work. It seems to be very difficult for active personnel executives, through their very sincerity, to write anything without preaching.

Lastly, the editor must be a good salesman. The things he has for sale are his own expert ideas. In many companies the editor has associated with him as a so-called "advisory board," a group of executives representing the various interests of his company. He must convince these men that they play an important part in making the magazine, but he must keep them in the position of advisors and not allow them to take the editorship out of his hands. That calls for some diplomacy, naturally. If he can do it, he changes his advisory committee from a nuisance into an asset. If the editor is well trained in his profession his job is not so difficult, although it takes time. After all, the editor is the expert dealing with amateurs.

What Does the Audience Really Want? What do the readers want? This can be summed up in a sentence. They want to be interested and there is no reason why they cannot be. The likes and dislikes of the audience of a personnel magazine are as varied as the likes and dislikes of readers of a newspaper, but they are all bound together by a common interest in the company through their positions in it. They want to know everything interesting which the company is doing. They want to know about their friends in the company who have moved to other towns. They want to know about

interesting things which individuals are doing in the company. They want to know when people are promoted as it strengthens their hope that they themselves may be promoted some time. They want variety—a balanced ration.

There are three main interests around which stories should be built—the jobs, the homes, and the pleasures. How interesting the stories are that are thus built up depends upon the skill of the editor.

How May the Success of Employee Magazines Be Judged? The best test, it seems to us, of whether the periodical is read is the reaction caused by lateness of the magazine. If there are inquiries when the magazine is late, if there are howls when an insufficient number of copies are received, then rest assured that the people are reading the magazine and want it. Another test is to see if any copies are left around the shop after distribution. If the magazine is not folded up and put into the pocket to be taken home, it is not successful. The best test of all is, perhaps, the spot check when properly conducted.

Common Faults of Personnel Publications. There are two faults which are widespread among employee magazines. First, they are often hybrid publications. Second, they are frequently dull. Many companies with a single magazine feel impelled to have that magazine perform both the functions of a magazine and a newspaper. This cannot successfully be done. It is our private opinion that a newspaper is the best single publication. The most important element in news is that of time. A magazine article on the other hand does not go stale for some weeks, perhaps months. Allow us to give an example of the difference in point of view between magazine and news writing.

Suppose a bowling contest were held at the works. The newspaper story would be "Bowling Contest Won by Team A" and would start off something after this fashion: "Last night in the Flatfoot Bowling Alleys, Team A, representing the Joiners and Wipers, nosed out Team B of the Darning and Patching Department. Thousands of members of the J. K. Gudgeon Ball Bearing Company witnessed the close of this annual event," and so on. The magazine story would be "Fine Points in the Art of Bowling—John A. Crosshatch, Captain of Joiners and Wipers team, Winner of Annual Bowling Contest, gives Tips to the Tyros." These two points of view are naturally incompatible.

In a number of companies now the monthly magazines are becoming real magazines and they are being supplemented by newspapers. The magazine of the Commonwealth Steel Company, for example, has two issues: a home edition which would appear to be a sort of monthly newspaper containing material of interest only to the people in the works, and an addition for outside circulation containing material written from the magazine point of view. This, too, is circulated throughout the works, and both magazines are well received.

The Illinois Bell Telephone Company has a monthly magazine and a weekly supplement which is in effect a weekly newspaper, printing all sorts of personals and covering all events in a timely, "newsy" fashion.

The Western Electric Company has a monthly magazine in its twentieth year in 1931 which is supplemented by six semimonthly departmental newspapers, professionally edited. All of these newspapers fit into the magazine and help to better it. They perform a function which no magazine with a circulation of eighty odd thousand could hope to perform.

Lack of Consideration for the Audience. We come now to the second point—that many personnel publications are dull. We find hackneyed thoughts on success written by officers. We find stories of an officer's trip to Egypt which might have been clipped from Baedeker. We find uninteresting talks given at conferences reprinted in full. We find a lack of balance, of variety—a too frequent mention of officers—a lack of originality in make-up and in writing.

Many of these things are doubtless due to short-sightedness of management. However, management is not entirely responsible for the poor stuff which appears in employee publications. Of course, the contributors are amateurs and it, therefore, devolves upon the editor to train as many writers in his company as he can. This is hard work and perfectly thankless, yet an editor worthy of the name will make an effort in that direction merely in order that he may produce interesting material for his magazine. He should set a high standard, for the sort of material he prints is the sort he is going to receive.

In the Western Electric News there was printed rather against the judgment of some executives who could not see any company bearing in the story, an article on "Raising and Hybridizing Delphiniums." The delphinium, incidentally, is a flower—the hardy larkspur. We explain this because the last time we told this story someone thought that delphinium was a kind of metal like aluminum. This piece was written by a shop man who happened to have achieved quite a success as an amateur grower of this flower. As a result of the publication of the article, we received some 2,000 letters from all over the country asking for further details about the growing of the flower and begging for seeds of the particular strain which this amateur had developed, so that a similar attempt to create beauty might be made.

Universal Interest in Hobbies. There is a vast field to draw upon in hobby stories and you will be surprised at the number of people who are interested in the same hobby. A hobby is an escape from the reality of life. So is your magazine, in a way, an escape from the essential tedium of work.

Appropriation. There remains one more question. That is, how much ought a company to spend on employee magazines? What should be the amount of this investment in goodwill? It seems to us that the proper approach for the solution of this question is how much is it worthwhile for each company to spend each year, per employee in an effort of this kind? Is \$2 per year per employee right, or is \$5 per year per employee too little? Naturally this is a question for the individual company to decide. Once decided they should turn over the spending of the money to the editor, give him encouragement, cooperation, and a free hand.

If each editor had these, we doubt not that in a short time we could produce magazines which would compare favorably in interest and influence with the best sort of commercial magazines of the country.

INDUSTRIAL TOWN-SITE DEVELOPMENT AND ADMINISTRATION

BY THOMAS A. McDONALD, *Industrial Counsel*

Necessity for Town-site Developments. There has been much said and written concerning the problems of organization, particularly that phase relating to selection, placement, adjustment, and development of employees. But little that is definite and concrete has been presented on the subject of *accommodation* of personnel, which gives rise to the necessity for industrial housing and town-site development.

Companies Concerned. This question of industrial housing is a perplexing and important one to companies located in settled communities where there is an actual housing shortage, or where rents for satisfactory dwellings are beyond the means of employees. It is a *vital* problem to companies starting new enterprises in out of the way places, where practically no living accommodation of any kind is available. Because of the greater number of difficulties involved, we will consider the question here principally as it affects firms in the second classification. Companies in the first class will have many, although not all of these same problems, so that much of what follows will be applicable to them as well, and can be adapted to suit their particular needs.

Importance of Satisfactory Living Conditions. In answer to a questionnaire sent to various employers in twenty-five cities of sixteen states, the majority claimed that unsatisfactory living conditions adversely affected production. Henry Ford states in a recent article: "It has been the experience in our European shops that, given the same relative wages and conditions, the European workman is not at all inferior to the American"; thus implying that any existing inferiority has been due to wages and conditions rather than to the people themselves.

If this is the case in settled localities, it is very much more so in isolated communities, as many companies have learned to their cost. Granting that it is necessary and desirable to provide fair wages and working conditions in a plant in order to secure and retain intelligent, loyal, efficient workers, it is every bit as important to provide as satisfactory living conditions as possible, while keeping expenditures within reason. Since the ultimate purpose of developing an industrial townsite is to properly provide for the protection, the comfort, the health, the education, and the recreation of the people who dwell there, it is obvious that as serious thought and study should be given to this phase of the enterprise as to the organization and development of any part of the plant itself. Making men substantial, self-respecting workmen and citizens goes far toward making them cooperating factors in the success of any business.

Importance of Initial Plans. Unfortunately, very few towns are the result of sufficient planning at the start, because their founders rarely saw far enough into the future and so made no plan or provision for what might be required in five, ten, or fifty years. Where towns have been carefully planned and soundly managed, the results speak for themselves.

In considering the question as a whole, it would be well to point out, first of all, the advantages of a sound development as against the one probable dis-

advantage, namely, the cost, as compared to the actual direct money return on the expenditure, bearing in mind at all times that there are usually compensating factors, such as low costs for fuel and power, and decreased taxation.

Advantages of Sound Development. Some of the advantages under normal conditions are:

1. Contentment which results from wholesome living conditions goes far toward creating an attitude of mind that is conducive to individual as well as plant efficiency and morale.

2. Labor turnover is unquestionably reduced. Losing men with valuable training and having to train new ones is very expensive.

3. The skill, experience, and loyalty which accompany long, steady service undoubtedly tend to reduce costs.

4. A better selection of labor is possible.

5. Permanent labor tends to keep the wage scale within reason.

6. Poor living conditions, combined with insufficient means of physical, spiritual, and mental welfare have their effect on the worker's family. Discontent and irritability in his family react upon the employee, making him dissatisfied and resentful. Many troubles in the plant are directly traceable to unsatisfactory home conditions.

It is often said that the kind of people in a town governs the kind of town it is. It is just as true to say that the kind of town you have very largely determines the kind of people you will attract.

Standard Requirements. To provide conditions that will attract and hold intelligent, efficient, and loyal workers, the necessary requirements are more or less standard. Adequate provision must be made for:

1. Comfortable homes, hotel, and boarding houses, at rates employees can afford.

2. Healthful and sanitary surroundings.

3. Pure water and milk supply.

4. Good medical service and hospital accommodation.

5. Modern schools and playgrounds for children.

6. Police and fire protection.

7. Stores furnishing suitable merchandise at reasonable prices.

8. Churches.

9. Recreational facilities.

Before construction plans are settled, it is necessary to decide what the immediate requirements are, and to give consideration to the probable and possible future requirements.

Forecasting the Pay Roll. The first step should be a detailed forecast of the pay roll, showing the number of employees that must be provided for, the rates to be paid, and the number of employees at each rate. These may be loosely classified as staff, skilled, semiskilled, unskilled, and further subdivided if necessary. Then a careful estimate must be made as to the number of married and unmarried in each class. There should also be estimated the total number of children, divided into under school age, school age, and working age. In making up estimates, workers in the auxiliary units, such as school, stores, post office, bank, and medical service, must be included. This gives the foundation upon which to build the housing requirements.

Table I shows the detailed forecast of a pay roll used on an actual development, being based upon a study of several plants similarly situated.

TABLE I

Daily rate	Monthly rate	Staff		Skilled		Semi-skilled		Unskilled		Total		Grand total	Probable number of houses required
		Married	Single	Married	Single	Married	Single	Married	Single	Married	Single

Determining Number and Types of Houses and Other Accommodations. This table gives daily and monthly rates¹ for the various classes of workers; also a careful estimate of the number of married and single men under each rate and class, the totals, and the number of houses required. To these must be added the teachers, doctors, dentist, policemen, town-site employees, store, bank, post office, bakery, dairy, laundry, and any other miscellaneous workers not actually employed in the plant.

The number of children is more difficult to figure as it varies considerably, but is apt to average not less than one child of school age to each house, and one child of non-school age. The number of children of working age in a new community is not likely to average over 20 per cent of the number of families housed.

Schools, hotel, boarding-house, and hospital accommodation must be balanced against the percentage of houses actually built as compared to the estimated requirements. If many six and seven room houses are built, it is

¹ The average daily rate for these calculations works out at a trifle less than \$5 per day or \$130 per month.

safe to figure that at least one-third of the houses will have a single worker living there; that is, a son or daughter of working age or a roomer.

The next step is to determine the minimum reasonable standards for the types of houses as to size, number of rooms, style of architecture, materials to be used, kind of construction, number of each type, and total number to be built, with approximate costs. On this depends the accommodation that must be provided in the way of schools, hotel, boarding houses, hospital, and other facilities. The more houses provided, the greater the school and hospital requirements, and the less hotel and boarding-house accommodation will be needed for the same number of employees.

To take care of the unmarried men not accommodated in private homes or in the hotel, small boarding houses have proved in actual experience to be most satisfactory. These are cheaper to run than additional hotels, and the men much prefer the small boarding house, since this enables the individual workers to choose the class of accommodation they desire.

Careful study is required to secure a balanced program and, before final decision is made, the first cost of various plans and the amount of money available should be considered, as well as the cost of operation.

Permissible Rental. One of the most important factors to consider in determining the minimum requirements is the relation of the amount of money the employee can afford to pay as rent to the amount of the investment. (The same problem will present itself if houses are to be sold to employees

TABLE II

Daily rate	Monthly rate	Maximum fair monthly rental 20 per cent of wages	Annual rental
\$ 3.00	\$ 78.00	\$15.60	\$187.20
3.50	91.00	18.20	218.40
4.00	104.00	20.80	249.60
4.50	117.00	23.40	280.80
5.00	130.00	26.00	312.00
5.50	143.00	28.60	343.20
6.00	156.00	31.20	374.40
6.50	169.00	33.80	405.60
7.00	182.00	36.40	436.80
7.50	195.00	39.00	468.00
8.00	208.00	41.60	499.20
8.50	221.00	44.20	530.40
9.00	234.00	46.80	561.60
9.50	247.00	49.40	592.80
10.00	260.00	52.00	624.00
	273.00	54.60	655.20
	286.00	57.20	686.40
	300.00 and over	60.00 and over	720.00

later.) Regardless of actual cost of the house, the rental or sale price will have to be within the means of the worker, with the difference in cost—if any—being borne directly by the company. Otherwise, wages will have to be increased to meet the higher rents. The general practice is to pay the going wage and charge to operation any deficit due to difference between what employees can afford to pay and actual cost.

Various authorities state that workers can afford to pay from 15 to 25 per cent of total income for rent—the latter figure being used when heat is supplied. Where tenants supply their own fuel, 20 per cent should be the maximum for the average, and might well be less for the worker earning under \$100 a month, particularly if he has one or more children, unless more than one member of the family is working.

Table II supplements Table I and shows the daily rate, monthly rate, and what the permissible maximum rental would be, figuring 20 per cent of monthly income for rent.

Cost of Houses. A most important factor to be considered in determining minimum standards is the relation of the sum of money the employee can afford to pay as rent to the amount of the investment on the part of the employer.

Table III shows monthly earnings, permissible monthly and annual rental, based on such earnings, and the amount of money which can be spent on houses if the gross return is to be 12, 10, 8, or 6 per cent. It also gives the number of houses in each class.

TABLE III

Monthly earnings	Permissible monthly rental	Annual rental	Number of houses	Cost of houses based on gross return of			
				12 per cent	10 per cent	8 per cent	6 per cent
\$ 78.00	\$15.60	\$187.20	51	\$1,560.00	\$1,872.00	\$2,340.00	\$ 3,120.00
91.00	18.20	218.40	72	1,820.00	2,184.00	2,730.00	3,640.00
104.00	20.80	249.60	44	2,080.00	2,496.00	3,120.00	4,160.00
117.00	23.40	280.80	12	2,340.00	2,808.00	3,510.00	4,680.00
130.00	26.00	312.00	22	2,600.00	3,120.00	3,900.00	5,200.00
143.00	28.60	343.20	15	2,860.00	3,432.00	4,290.00	5,720.00
156.00	31.20	374.40	17	3,120.00	3,740.00	4,680.00	6,240.00
169.00	33.80	405.60	12	3,380.00	4,056.00	5,070.00	6,760.00
182.00	36.40	436.80	13	3,640.00	4,368.00	5,460.00	7,280.00
195.00	39.00	468.00	10	3,900.00	4,680.00	5,850.00	7,800.00
208.00	41.60	499.20	3	4,160.00	4,992.00	6,240.00	8,320.00
221.00	44.20	530.40	1	4,420.00	5,304.00	6,630.00	8,840.00
234.00	46.80	561.60	2	4,680.00	5,616.00	7,020.00	9,260.00
247.00	49.40	592.80	2	4,940.00	5,728.00	7,410.00	9,880.00
260.00	52.00	624.00	11	5,200.00	6,240.00	7,800.00	10,400.00
273.00	54.60	655.20	6	5,460.00	6,552.00	8,190.00	10,960.00
286.00	57.20	686.40	5	5,720.00	6,864.00	8,580.00	11,440.00
300.00 and over	60.00 and over	720.00	12	6,000.00	7,200.00	9,000.00	12,000.00

The Town Site as an Investment. As an investment, one would expect the rental to cover interest on capital 6 per cent, depreciation 3 per cent, insurance $\frac{1}{2}$ per cent, maintenance 2 per cent, or $11\frac{1}{2}$ per cent; plus taxes ranging from 1 per cent to as high as 5 per cent, depending upon the amount of taxes the plant pays to the town. Estimating taxes on houses at $2\frac{1}{2}$ per cent gives a total figure of 14 per cent.

Very few companies will admit that they lose money on their housing, but an analysis of actual figures from several companies shows that the one getting a gross return of 10 per cent or better is a rare exception, and some get less than 6 per cent gross. If a company gets a gross return of 8 per cent this would, on the average, cover depreciation 3 per cent, maintenance 2 per cent, taxes and insurance 3 per cent; or if nothing were figured for depreciation, there would be 3 per cent for interest. If the cost of the lower rental houses resulted in a return of less than 8 per cent, this difference might be made up on rentals of the higher grades.

Types of Houses. Types of houses may be classed as follows, in order of preference: single houses, semidetached, duplex, row houses, and apartment houses. There is always an insistent demand for the single house, but it is the most expensive to build. The row house, that is, several houses with a party wall between each two houses, and two rooms deep upstairs and down, is a cheaper house to build, but obviously has many disadvantages and should be avoided if possible. The single house and the semidetached two-family houses, both of one and two stories, seem to give best satisfaction.

As to number of rooms, a distribution of 20 per cent four-room, 30 per cent five-room, 30 per cent six-room, 15 per cent seven-room, and 5 per cent for special houses should suffice, unless there are some unusual conditions. As it is not customary for more than 65 per cent of total requirements to be constructed the first year, any lack of balance can be corrected later.

For the unskilled and some of the other lower paid workers, the floor plan should be laid out to provide a good-sized kitchen and a good-sized living room, which can also be used as a dining room; sufficient closet space; a large bedroom for parents and infant children, a bedroom for the boys, and one for the girls. A bath room and toilet should be provided; also arrangements for heating with stove and for running water. These houses can be built without cellars, but on a solid foundation. An enclosed porch on the rear can be used for coal, wood, and other storage. The omission of parlor, cellar, and front porches will cut down the cost considerably. Heating these houses with stoves will make the fuel bill much lower for the tenant.

For the skilled workers and staff, additional facilities such as separate dining room and living room, cellars, larger closets, wash basin in bath room, furnaces (or hot-water heating), laundry tubs, and porches can be provided.

Construction and Design. The kind of material used and the method of construction will depend to a large extent upon the locality. There is little saving in total overall cost by using poor material or poor construction methods, for what is saved on original cost is more than lost on maintenance, over a period of years. Details of construction cannot be gone into here, except to say that houses should be comfortable, have well insulated walls, and sealed floors and roofs.

In considering exterior design, it is well to realize that there can be beauty as well as economy in simplicity. Houses need not be elaborately festooned, with valled, dormered, or angled roofs and scroll work. Good variety can still be secured without departing from the square or oblong type houses, with well-proportioned openings, a proper blending of colors, and well spotted with regard to the topography and the surrounding houses. Some of the most attractive towns, on close scrutiny, prove to be a collection of simply designed houses plus well-planted shrubbery and shade trees.

Physical Layout. There seems to be an impression that the first step to take in laying out a town site is to clear off all trees and shrubbery. This is a great mistake. Why destroy one of the most valuable natural assets, and then wait years for new plantings to develop? Clear off only what is necessary and utilize the balance.

Planning the physical layout of the town must be done very carefully, as mistakes made at the start are difficult if not impossible to correct later. Experience in many instances has proven the advantage of securing in the beginning the services of an experienced and competent town planning and landscape engineer with a history of success. If he is also an architect, so much the better. In any event, the engineer and architect must cooperate fully if the final plan is to be all that can be desired.

The plan must provide for roads, lanes, walks, sewers, water lines, location of dwellings and other necessary buildings, as well as for parks and playgrounds.

The land needed for all possible future requirements should be secured, along with control of all land within reasonable distance. Most companies fail to do this and have to pay ridiculous prices later for land that could have been secured for a few dollars an acre. In addition, satellite communities must be avoided; that is, shack and shanty developments on the borders of the town, unsanitary and offensive in appearance and a menace to the health of the community. These usually spring up when there is a shortage of accommodation, when rentals are beyond means of workers, or where practically no provision is made for some class of workers. However, this can be controlled (even though housing provision is not made for all workers) and can be made one means of substantially reducing the capital expenditure. The method of doing this, however, so much depends upon local conditions, upon the class of workers, upon the financial status of the company, and upon the policies of administration to be adopted, that no definite method should be proposed without considering in detail all or most of these factors, since the company's total expenditure is so greatly affected by the policy adopted here.

Zoning Areas. In order to concentrate residences, business, and industries, each should be confined to certain definite areas. Where practicable, the plant is usually at one side of and a reasonable distance away from the town. The business section is usually near the center and serves as a dividing line between different residential sections. It provides for stores, offices, bank, post office, and public buildings. There may be two, three, or more residential sections, each one providing for a different class of houses.

When practicable, the plan should be so arranged that the extension of sewers, water lines, roads, and walks can be economically expanded as required.

Problems of Administration. As soon as the organization is ready to operate, it is confronted with the various problems of administration. These, of course, will depend largely upon the type and size of the organization and the conditions in the particular locality. There are certain questions, however, which are bound to arise and which must be anticipated. For example: How can one arrive at a fair basis of rental? What are rents to be based upon? How can one allot houses so as to give general satisfaction? Who shall allot houses? (A very vital function.) What is the best method of keeping down cost of maintenance and still not have dissatisfaction? How can one avoid discontent on part of tenants who want transfers which are not justified because of increased expense? How can one do special work that seems justified in some cases, without inviting an avalanche of requests from tenants similarly situated? How can one induce tenants to keep up appearance of grounds? How can one increase rentals that are too low, and still keep tenants satisfied? Is it advisable to let employees have a voice in the municipal government? What are the dangers and the advantages in connection with this? Regarding stores: Which is best: to allow outside merchants to open stores or to run a company store? If the latter, on what basis should it be operated?

Space will not permit detailed discussion of these points, but it is important to emphasize the fact that policies for carrying on the administration of town-site affairs must be formulated in such a way as to give satisfaction to all concerned, at not too great expense to the company. Definite standard policies are very essential because of the necessity for consistency. It is imperative to bear in mind that everything done in the beginning establishes precedents, which may prove to be vital factors in the ultimate success or failure of the enterprise.

Closed Town or Open Town. It may be desirable to touch very briefly upon the question of a closed or open town, since this also is one which needs to be considered in the early stages of a town-site development.

Until all plans have been settled and a definite program decided upon, there is a distinct advantage in having complete control of the town. However, there are many disadvantages to retaining permanent control. In most cases the government will give little or no financial assistance to a town entirely owned by a company; whereas in an open town it is frequently possible to secure substantial contributions toward schools, hospitals, and other public buildings, as well as roads. In addition to this, an open town can often issue bonds at a low rate of interest, guaranteed by the government, for payment of sewers, water works, roads, and other municipal improvements.

Furthermore, if it is the desire of the company to encourage employees to build or purchase their own homes as the town develops, in order to limit its own expenditures, an open town is desirable. Very few people want to own property in a closed town.

The double role of sole landlord and employer is a difficult one to fill. Full company control of not only the homes but also of the administration of

the government, the stores, and the public service means that all the people are tenants or boarders. Most of the initiative, interest, and feeling of responsibility that flourish in a community of home owners are absent, and building up civic pride is a big problem. However, companies have occasionally succeeded in doing it, while many others have failed completely.

Carrying Out the Plan. The development of a town site is by no means a slight undertaking. No town can afford to do everything at once, but every town should try to accomplish at least one big thing each year. A definite program should be mapped out, and an attempt should be made to follow it, always looking to the future. The accomplishment of one company, in an entirely unsettled community, over a period of twelve years will illustrate this point.

During the first three years a start was made with a definite plan for the town; then came some houses, water, sewers, and fire protection; next, good schools, good roads, an athletic field, and tennis courts. The fourth year saw a new hotel; the year following, fifty more houses; next, a fine skating rink; during the next three years, seventy-five more houses. In the tenth year they completed one of the finest hospitals in the country and a curling rink. And with the following year came the opening of a nine-hole golf course, more houses, and a magnificent hall. In almost every year some work was done toward improving the appearance of the town by planting trees, flowers, and shrubs, as well as adding to the parks and boulevards.

Sharing Responsibilities. A program which provides for growth from year to year helps to quicken the interest of all concerned and to sustain the enthusiasm which comes through the joy of gradual unfoldment. It also affords opportunity to secure the cooperation of the townsfolk in connection with various community activities, which is exceedingly desirable because men, women, and children will all have greater satisfaction and pride in the town if they feel they have really had a hand in its making.

A definite plan to delegate to committees of the workers certain phases of the work having to do with civic, educational, and recreational affairs creates a bond between management and employees which fosters a deeper spirit of cooperation throughout the organization. It is worthwhile, therefore, to make the formation of such committees a definite part of the plan for carrying out the advanced stages of a town-site development program, bearing in mind the fact that men value most the things they strive for.

CHAPTER XI

COLLECTIVE BARGAINING WITH UNIONS

By F. A. SILCOX, *Director of Industrial Relations, New York Employing Printers Association*

Determination of Policy. The first problem management faces in any relation with trade unions is one of the determination of the general policy. There are three possible courses to take: (1) to accept the trade union as a part of the industrial structure and work out a constructively comprehensive plan of cooperation; or (2) to accept the trade unions under compulsion and make the most of the situation; or (3) to resist and operate on a non-union basis. Factors inherent in the locality or in the industry will in most cases be the basis for this policy decision. Among the most important of these factors are:

1. The number of plants in the locality operating on a union basis.
2. The percentage of production volume represented by the unionized plants.
3. The number of craft unions in the industry.
4. The necessity for joint discipline—control to effect industrial stabilization.
5. The strength of the unions through their controls of skill.
6. The available supply of labor and the time necessary to train skilled workers.
7. The character of union leadership, its history and record for dependability.
8. The degree of jurisdictional authority exercised by existing unions in the industry and the possibilities of conflict.
9. The control of the local unions through their international organizations.
10. The competitive rates of wages in plants not union and those paid by plants in the same locality or in a competitive field.

Upon the basis of these primary factors, management must decide the advantages and disadvantages of operating on a union or a non-union basis.

Unionism, Effect on Output. Limitation of output is not inherent in either union or non-union operation. Limitation of output in its various forms is usually a protective device based upon fear of unemployment. With this fear removed, it is possible to release the capacity of the working forces. Under union conditions the protective measures set up are more effective in operation, to the extent and degree of strength of the particular union or unions in the case and the existing conditions of the labor market. In a short labor market the strength of the union is increased through the possible

choice of outside jobs open to the employees, and it is the problem of the management of the particular plant to insure itself through satisfactory relations and working conditions. In a long labor market the fear of unemployment may make for temporarily increased production because of the lack of the alternative of other jobs. The only effective method to secure maximum production with trade union labor is to build up a relationship based on mutuality of interests and confidence between men and management.

Unionism and Employee Representation. Unionism is founded upon the belief of employees that in order to secure certain wages and working conditions they must place themselves in an economic position sufficiently strong to secure such conditions through the complete withdrawal of their work if necessary. In the withdrawal of their labor, financial support is obtained by previous pooling of defense funds in a nation-wide organization. In addition to this protection, many unions offer death benefits, out of work relief, protection against unjust discharges, and the like. Employee representation in a plant, which is an integral part of an industry, must offer, to be effective in the long run, an equal or more attractive alternative to employees than that which the trade union offers. Plans for securing representation for employees are in essence of two kinds: (1) an employee organization with no union contracts or operating entirely independently of any contracts that exist, or (2) the use of the joint conference principle together with union recognition. The character and structure of any employee representation plan will in itself determine whether it is reconcilable with trade unionism. Where the union is recognized as a part of the industrial structure there appears to be no sound reason why a plan of plant employee representation need be irreconcilable with unionism. In one case, that of the agreement of the Baltimore and Ohio Railroad with the shop craft unions, a plan of union and plant employee representation has been tried and has been found to be successful in promoting effective working relations resulting in increase of efficiency, the elimination of waste and the minimizing of misunderstanding. The Baltimore and Ohio plan is definitely suggestive as a constructive effort to secure the advantages of an employee representation plan worked out in cooperation with the unions.

Unionism, Effect on Wages and Working Conditions. If the unions are of long standing and well entrenched through the control of skill, the undoubted effect is to establish standards of wages and working conditions. There is no absolute in wages and working conditions by which union wages and working conditions may be measured or determined on any preconceived basis. The practical effect of unionism is to secure both wages and working conditions to the limit of its economic strength. Usually, in a locality where the unions are strong the result is to establish through collective agreements standards which serve as the basis for wages, hours and working conditions in the community in which they operate. Plants operating non-union are, to a more or less degree, affected, depending on the extent of union control. If the union control is strong the natural effect is to use that strength to the limit to raise the rates of wages, shorten hours, and improve working conditions from the employee's standpoint. Union demands may for short

periods force wages and working conditions beyond what an individual plant or an industry can economically stand. Usually the balance is restored if jobs are lost and the demands secured prove in the long run to be detrimental to the union and its members. It is axiomatic that in the long run a group will not act contrary to its own interests.

Collective Bargaining as an Application of Industrial Law, Effect on Discipline and Authority. To secure uniformity of wages, hours, and working conditions through the major portion of any highly competitive unionized industry, particularly one made up of a large number of small units, experience has shown that joint disciplinary action is required on the part of a strong employers' association and strong unions. Gradually, between the two forces, a code of industrial law is built up, through joint interpretation of issues in current cases, and law is enforced through joint disciplinary action. The plant is guaranteed against any interruption of work when it conforms to the laws laid down by the joint committees representing the employers and the unions or, on the other hand, if the plant fails to conform, the unions are released from their contract obligation and may use the strike, if necessary, to enforce the decision. In industries in which collective bargaining has been operative over any extended period of time extremes seldom have to be used to enforce discipline, both employers and the unions accepting the joint decisions, their experience dictating that it is to their own best interests in the long run to maintain order in the industry of which they are a part.

Definition of "Closed Shop" and "Open Shop." By closed shop is meant a shop employing only union workers. No work coming within the jurisdiction of the unions represented is allowed to be performed by anyone not a member of the unions. It is based on the practical assumption of the unions that in order to maintain the standards set up under collective contracts they must control the working personnel.

The open shop is one which is open to both union and non-union workers. The open shop is based upon the employers' assumption that he has the right of freedom of individual contract with labor whether union or non-union.

Stabilization of Costs by Union Contract. A large item, in some industries the largest single item, in cost of production is labor. In highly competitive industries it is of vital importance to predetermine, fix and maintain with uniformity between plants the wages, hours, shop practices, and working conditions which affect labor costs. This is accomplished in unionized industries through joint collective contracts which set forth the standards and provide the machinery of enforcement.

Nature of the Unions, Union Functions. There are, generally speaking, three types of unions:

- a. Craft unions.
- b. Industrial unions.
- c. Labor unions.

a. *The craft union* is an organization of wage earners engaged in a single occupation or task. It may include at times a number of closely allied tasks or crafts. Such a union usually covers but a fraction of the work of a given indus-

try. The craft unions in different localities are usually united into a national or international organization which serves to integrate all of the various local units into one general body. Examples are the International Typographical Union, the Brotherhood of Locomotive Engineers, and the like. These craft unions are further federated in city federations, state federations, and national or international federations. Examples are the Chicago Federation of Labor, the Illinois Federation of Labor, and the American Federation of Labor. In each of these federations, the constituent organizations retain their individual independence or sovereignty.

b. The industrial union is a type of organization designed to include all workers in an industry rather than those simply in individual crafts or trades. Its usual units are the local, the district, and the national or international industrial union.

c. The labor union is a type of organization designed to include all workers regardless of craft or industrial divisions into homogeneous groups, by localities, by districts, and throughout the nations or the largest possible international area.

The functions of all of these types are generally, through economic solidarity:

1. To secure improved wage conditions.
2. To secure shorter working hours.
3. To insure security of employment.
4. To protect members against arbitrary, autocratic action by management.
5. To give relief to members in case of loss of employment, injury, sickness, and old age.
6. To secure the enforcement of agreements.
7. To provide machinery for the settlement of disputes.
8. To exercise some control on the introduction of labor displacing machinery.
9. To limit the number of apprentices.
10. To force by strike when necessary, financed by defense funds, recognition of the union and its demands.
11. To give voice through representative organizations to political expression.
12. To promote a wider opportunity for members to participate in the democratic control of industry.

These objectives and their many corollaries in every variety and combination exist as functions. Policies vary from the orthodox craft union, asserting its right to bargain collectively with employers to achieve these objectives through agreements, to the revolutionary type of labor organization which has as its objective the overturn of the social order.

Union Leadership. The quality and type of leadership in any union is a reflex of the conditions the union has to meet, the character of work done, the racial background of its membership, and similar factors. Obviously, the type of leadership in an organization of composers in the printing industry, through whose heads and hands pass the news and the scientific, literary, and dramatic productions of the day, will be different in quality and kind from the leadership developed in a longshoreman's union. So too the leadership of a union made up largely of people from politically repressed foreign coun-

tries will vary in kind and quality from one largely composed of native-born, English-speaking people

Where the union is fighting for its existence, the leadership must, in order to lead, reflect this condition. Where the union is accepted as part of the industrial structure, the fighting leadership is replaced by a business type of leader. In any case leadership of a trade union is secured through the exercise in varying degrees of the same general abilities which capture leadership in other fields. Through contests, sometimes of extreme bitterness, the labor leader emerges seasoned with experience to represent the membership of the union. Through such contests and experience a union leader secures an industrial point of view, whereas many of the employer leaders having to deal collectively with the unions secure only an individual plant point of view. This is a real factor in collective negotiations between the employers and the unions. To meet this effectively, the employer must deal through an organization of his industry which is equipped to ascertain the facts and make them available for use by the employers in negotiations with the unions.

In unions as in other types of organizations, there occurs at times leadership of the racketeering character, the sole purpose of which is to exploit the organization for personal ends. Such leadership exists in many cases because of profitable collusion with racketeering employers. Drastic action to purge the union of such leadership has to be taken to reestablish responsibility and industrial order.

Leadership of the unions will be forced in the future to develop, because of the rapidly changing industrial conditions, a more scientific approach to the problems of the industry of which they are a part. Introduction of new machinery, scientific management for the better use of materials, and elimination of waste are factors which will force the union leader to deal with these problems constructively or management will have to turn to other alternatives of labor policy. In any case, it must be remembered that the leaders of a union as of other groups cannot go beyond the ability of the general rank and file to keep up. The spear head can travel no faster than the shaft.

Intraunion Problems, "Inside Politics." The leadership of any mass movement requires an understanding of the motives which inspire men to action; the fears which hold them in check; the passions which arouse them to revolt; and the satisfactions which calm and steady them. These factors in varying degrees a union leader must realize and capitalize if he is to maintain leadership. Divisions within the ranks on objectives and the means of obtaining them give rise to political groups within the union. These different groups play for the power of control by endeavoring to elect leaders who will express their respective aims. These aims may be radical, conservatively progressive, or stand pat. Cleavages, in general, may exist because of certain differences of temperament, religion, racial, or other fundamental factors. This is the fabric of the "politics" of the union. Because of the questions involved, those of jobs, wages, working conditions, living standards, hours, and the like, union political controversy is on the whole more intense than in organizations whose aims are not so sharply focused on vital bread-and-butter economic issues. The union leader must, if he is to lead, play politics.

If he plays the various forces in his organization constructively for the promotion of the interests of his membership and the industry of which he is a part, he may rise to the capacity of statesmanship. If he plays such forces in his organization for personal gain, he may become a sinister factor both in the union and in the industry.

Meeting exigent conditions as they arise, he must to a considerable extent be a pragmatic opportunist. He may know that a certain action is right but that the inside politics of his organization would effectively block him if he attempted to take that action. Sometimes it is necessary to resort to arbitration and have the arbitrator in the case bear the criticism; sometimes it is necessary to wait until conditions are more favorable for action. It is of especial importance that in any collective bargaining situation, whether it affects wages, working conditions, or what not, the management employer group have a seasoned, sophisticated, and reasonably complete knowledge of these political factors inside the union. In many cases, they will determine the result of the negotiations more than the economic issues involved. The responsibility of management is to see that its most experienced leaders are chosen to carry on negotiations or the settlement of current disputes with the unions. Their decision will determine in many cases whether a contract of mutuality of interests will be agreed upon; whether or not the industry will resist because of unreasonable demands; whether or not arbitration must be resorted to; and whether or not the foundation is laid for long time cooperatively constructive relations. In this, management has its own inside political situation to deal with involving inherently some of the same problems the union leadership faces. Any effort on either side to control the inside politics of the other side is dangerous in the long run in that such practices usually result in corruption on both sides.

Interunion Problems; Jurisdictional Disputes; Sympathetic Strikes. Jurisdictional disputes which give rise many times to bitter conflict between the unions themselves and the unions and the employer involve in essence the same elements that are inherent in commercial conflicts for the control of raw materials, markets and prices. For economic self preservation, the union sets up jurisdiction over a certain class of work and builds up its organization on that basis. Any breakdown of that jurisdiction by invasion by other unions threatens not only jobs for their membership, their standards, the training of their apprentices, and the like, but the very life of the organization itself. These are the reasons why invasion of jurisdiction is so stubbornly and bitterly contested, many times resulting in open conflict and warfare. Changing methods and mechanisms in recent years have accentuated this perplexing industrial problem. A classical case is the change in building construction from wooden window frames to metal—the carpenters claiming jurisdiction by the traditional right of possession and the sheet metal workers through technical classification. Another is that of the erection of iron smoke stacks. The structural iron workers claimed jurisdiction because of erection in the air; the boiler makers because they required tight riveting—the work of the boiler maker. In a short labor market with plenty of jobs, the conflict over jurisdictional questions usually abates. In a long labor market with jobs scarce, men will fight on to the extent of killing each other

because it means literally bread and butter for their families. It is management's function first to understand why these jurisdictional questions arise, why they occasion such bitter conflicts and then to set up collectively cooperative industrial machinery which will serve to prevent the difficulty, and, if that is not possible, to localize the trouble so that the conflict will not spread through sympathetic strikes to the entire industry. One of the best examples of constructive effort to meet this problem is in the building trades which industry, because of the wide variety of crafts employed, is peculiarly beset with difficulties of this nature.

The sympathetic strike is a strike of a related union or unions to assist a union on a direct strike. It is a device of correlated labor unions to protect themselves by taking the offensive to assist a union on strike. Usually it will be found that unions having satisfactory wages and working conditions have some compelling reason to call a sympathetic strike; it is obvious that they cannot escape the realization that by such action they place themselves in jeopardy of losing what they have gained. Mere condemnation of their action does not escape the issue. It may become necessary to use drastic measures to stop the spread of a conflagration of sympathetic strikes in an industry. It is a challenge to management to use preventive measures where possible.

Unions in Business; Labor Banks. An analysis of the various union ventures in the field of banking indicates quite clearly that if they conduct these banks on sound banking principles with capable bankers there is no inherent reason why such banks cannot be successful. The danger lies in the use of the large collective funds of the union in banks dominated by union political leaders and not by bankers. The expectations of the promoters in many cases that labor banks would be used to assist employers who might be placed in jeopardy because they are "fair" to the union; that the unions would become educated and experienced in business management; that unions would capture through their collective money power seats of control in industry, if not ownership, have not been realized. On the contrary, indications are that the movement has slowed down as the result of some rather disastrous experiences and will take a long time to recover if it ever does. Those labor banks that still survive do so by following the standards laid down by the conservative old-line banks.

Unions and the Immigrant. The composition and complexion of many of the unions have been determined by the flood of immigration which poured into this country during the years when there were only limited restrictions to entry. Some of the unions were made up almost wholly of old world craftsmen with their racial, religious, and political inheritances. The unions, strengthened by the war and affected vitally by the let-down which followed, besieged Congress to limit immigration in order to prevent flooding the American labor market. This effort combined with other factors resulted in limiting immigration by an assignment of quotas to various countries. The rapid development of automatic labor-saving machinery has been no small factor in promoting restrictions on immigration. The gradual development of craftsmen in this country to do effectively the work done by skilled workers from Europe was another factor. The unions throughout this period

of unlimited immigration had not only the economic problem to face but a tremendous problem of education of their foreign-born members. With the second generation this situation is changing and it can naturally be expected that the character and outlook of many of the unions will change. It is important to understand the historical significance of this background of American unions with their heterogeneous membership in comparison with the homogeneous character, for example, of those in England. To understand why certain conditions exist among the unions of this country, their objectives, their points of view, and the like, must be weighed as factors entering into the question of dealing with these unions. It is a responsibility of management to have historical perspective on vital questions of this character.

Collective Bargaining, the Contract. The purpose of a collective contract is to set forth terms and conditions agreed upon as the most effective working compromise between the organized union on the one side and the organized employers association or the individual employers on the other; it is the self-imposed labor law code of the particular industry setting forth a reasonably well balanced series of premiums and penalties. Within the contract as an inherent part of it must be set up the machinery for joint enforcement, maintenance of industrial discipline and the settlement of disputes which arise over the interpretation and enforcement of its terms.

Specifically the contract should include:

1. Identification of parties.
2. Definition of jurisdiction.
3. Duration.
4. Settlement of disputes.
5. Working conditions.
 - a. Hours.
 - b. Lunch periods.
 - c. Holidays.
 - d. Overtime.
 - e. Payment of wages.
 - f. Quitting work, lay-offs, and discharges.
 - g. Foreman and his authority.
 - h. Character of work to be performed.
 - i. Complement of men on various types of machines.
 - j. Apprentices.

Supplementing the contract should be an arbitration agreement setting forth procedure to be followed in the settlement of disputes which cannot be settled through the joint conference committees set up in the contract itself. By formulating the wage-scale contract and the arbitration agreement as separate instruments but with each instrument making reference to the other, it is possible to modify either one without affecting the other.

Before entering into a collective labor contract, contracts in use in various industries should be carefully studied to determine the most effective form to be used and to realize on the experience of those groups which have had agreements over a fairly long period of time. It is necessary of course to

adapt the contract form to include that character of substance which is suited to the particular groups involved.¹

Under any collective contract relations the joint machinery for interpretation, enforcement and settlement of disputes is of especial importance. A suggested form of structure for such joint machinery may be briefly outlined as follows:

1. A joint conference committee made up of equal representation from the union and the employers with voting power equal—a majority of each side to be secured for a decision. Upon failure to agree, the procedure for adjudication to be through the selection of a jointly agreed upon arbitrator whose decision is to be final and binding on both sides. This is the supreme court of the contracting parties. The jurisdiction of this joint committee covers:

- a. Grievances involving alleged violations of contract.
- b. Interpretation of contract clauses.
- c. Terms of the introduction of new machinery and processes.
- d. Renewal, amendment, expiration of agreement.
- e. Any special matters involving precedents to be established for the industry.

2. A joint discharge committee made up of equal representation from the union involved and the employers association. A majority vote of each side required for a decision. The jurisdiction of this committee to cover:

- a. The final adjustment of discharge cases which are brought up on appeal by the plant or union member through their respective organizations. It is important that the right of discharge should be vested in the foreman subject, in order to avoid abuse, to review by the joint discharge committee if asked for by either party.
- b. The outlining of procedure governing the trials of discharge cases and the laying-down of rules to guide the employers and the employees parties to the contract.

3. A joint apprenticeship committee made up of equal representation from both sides—a majority vote of each side to be necessary for a decision. Provision to be made for the selection of an arbitrator if deadlocked or for reference to the joint conference committee if the question involved requires an interpretation of contract. The jurisdiction of this committee to cover:

- a. The study, investigation, and report on the enforcement of the apprentice regulations as set forth in the contract.
- b. The trial of apprentice cases with full authority to cancel the apprenticeship in cases of lack of aptitude, delinquency, or violations of discipline—subject to the general conditions as set forth in the contract including:

Ratio of apprentices.
Regulation of apprentices.
Qualifications.
Term.
Jurisdiction.
Duties.
Grading.

¹ The Taylor Society through a special committee has set forth in a proposed "industrial employment code" certain minima which might serve as a guide in the drafting of contracts; presented in tentative form at a meeting, Dec. 5, 1930.

Education.

Discipline.

4. Administration of the contract.

- a. By individual employers and the union.
- b. By employers association and the union.
- c. By permanent boards appointed by the industry in question in one city or region.

Administration of the Contract. 1. *By Individual Employers and the Union.* Unless the individual employer is one in a locality in which there are no other plants dealing with the union, or there are other limiting factors, he should join his employers' association in order to provide effective joint machinery to protect his own interests. If he must deal individually with the union, he should insist on an arbitration agreement either as a part of or supplemental to his contract in order for him to have the means of settling any disputes or grievances with the unions. With such an arbitration agreement the set up should be equal representation on a joint conference committee for the plant and the union with a majority vote of each side necessary for a decision, in cases of deadlock the matter to be referred for final decision to a mutually selected arbitrator. It would be advisable for the plant to designate someone in its organization to deal with the union representatives for the investigation of the facts in cases, and to adjust the case if possible without bringing the matter to the joint committee.

2. *By Employers Association and the Union.* In an industry covered by a collective contract, the individual plant is included through membership in an employers association. Within the plant unit each union has a representative, usually elected by the members of the particular union in that plant. Minor grievances are taken up by the union plant representative with the foreman, and cases not involving precedents or new interpretations of contract are usually settled without going to the joint committees. Upon failure to agree, the union representative refers the matter to his organization and the foreman through the management to his employer organization. The next step is for a representative of the union and of the employers association to investigate the facts and make a decision in the plant, if the case does not involve a precedent or a new interpretation of the contract. If the plant or the individual union member involved disagrees with the decision, the case is brought before the joint committee having jurisdiction as defined by the contract.

To make the above machinery effective in practice, it is necessary for both organizations to maintain representatives currently to carry on this work. Usually it is done through the paid officers of the union and in the employers association through an individual assigned to this work or, depending on the scope and content of the industry, through the establishment of an industrial relations department with a director. The functions of such a department are:

- a. To study the entire situation governing the relations between the industry and the unions.
- b. To get all pertinent facts affecting this relationship and have them available for the employers' committees.
- c. To investigate all individual cases of dispute and make rulings in accordance with contract conditions.
- d. To prepare cases for arbitration and assist in the selection of an arbitrator.

- e. To rewrite contracts for submission to wage negotiating committees.
- f. To supervise the machinery set up for the education of apprentices and report to the employers' apprenticeship committee recommendations for improvement.
- g. To promote good will through confidence and at the same time protect the interests of the plants represented in the association.
- h. To carry on special production studies on different types of equipment with special reference to the manpower needed and skills required.
- i. To arrange joint committee meetings for handling of all cases.
- j. To assist the employers association in securing additional eligible members.
- k. To act in general secretarial capacity keeping minutes, records and other supplemental work in this field.

3. *By Permanent Boards Appointed for the Industry in Question in One City or Region.* This plan of joint enforcement machinery is best exemplified in the men's clothing industry. Instead of depending upon joint committees set up within the industry itself and the selection of a combination conciliator-arbitrator when needed, a permanent board with an arbitrator jointly selected and paid by both parties is used. Union representatives are elected by the members in each individual plant and minor cases are settled as they come up, both sides having the right to go to the arbitrator if a settlement is not reached. Representatives of both the union and the employer appear before the arbitrator and present the facts. The conciliator-arbitrator, acting under the stipulated conditions agreed upon by both parties, endeavors to reach a settlement through conciliation; if he cannot, he has the authority to make the decision.

The plan has the advantage of securing arbitrators' decisions which have some continuity and obviates the difficulties involved in selecting an arbitrator in each case as needed. On the other hand it has the disadvantage that the representatives of both parties refer cases for settlement which it would be conceivably safer in the long run to have decided by men actively engaged in the industry as under the joint conference committee set-up.

Strikes, Boycotts, and Disputes over the Union Label. A strike, like a declaration of war, is the resort to the ultimate test of strength for the determination of an issue, the settlement of which is either not justiciable or for which the justiciable machinery is lacking or has failed. War declaration of a defensive character is made when there is an invasion of territory or there is a challenge to sovereignty. Reversely, offensive war is usually either to invade territory or to challenge sovereignty. Strikes, in the same category as war, are both offensive and defensive. The unions as a collective group use the strike to secure if they can a greater share of the economic income. To achieve recognition when it is denied, the union resorts to direct action as a method to establish its "place in the sun." If attacked by an invasion, to reduce wages, the strike may be used to avoid the action or to force a compromise. If an effort is made through a lock-out to break up the union and substitute non-union labor, then there arises an inevitable conflict unless the union is too weak to resist. The causes of strikes are of course many and varied. In the last analysis, however, they can be partly classified defensively or offensively under the two broadly general causes, either invasion of territory or challenge to sovereignty. The strike may be untimely;

it may be ill-advised; it may fail in its purpose; it may invite public condemnation or public approval and support. In any case, the events leading up to the strike, the complex of motives and the economic issues involved, must be objectively understood if the conflict is to be settled with the minimum of loss to all parties involved. Direct action conflicts occur over wages, working conditions, hours, recognition, jurisdiction, introduction of labor-displacing machinery, secession of local unions, and other vital issues. Strikes are costly to both sides and ordinarily with a fairly even balance of power with the outcome doubtful there is the tendency to use less costly methods, conciliation or arbitration. If the union has the balance of power the tendency is to use it to the full extent at the time either through the constitutional channels set up, which they naturally endeavor at the time to control, or through direct action of the strike.

The primary counter offensive and defensive measure used by the employer group, the lockout, is essentially the same in principle as the strike. Both are extreme measures used as a last resort to exercise control to force a more satisfactory workable compromise when other methods have failed.

The boycott is the use of economic pressure without open conflict to force terms. It is an effort to practice the blockade to cut off supplies and force one side or the other to submit. One side or the other uses its economic strength through the withdrawal of its purchasing power, refusing to buy or use goods or employ labor, or shutting off sources of supply. It is the use of the siege to starve out the opponent without resorting to the use of direct force. Like the set up in the covenant of the League of Nations, the economic boycott is a preliminary measure to force terms and if unsuccessful there is the avowal that the next step is open and direct action in the form of war to settle the issue. There is no general rule which can be followed to wholly avoid the use of these weapons. There is the opportunity with a full understanding of causes to arrive at working compromises without resorting to open conflict. This requires a constructive program and a promotion of reciprocal interests.

The union label is the "trade-mark" of union labor used to indicate that the goods which bear this label have been manufactured under conditions approved by the union as fair. It is used by the manufacturers of goods to invite the purchase by members of organized labor of their goods or to avoid resistance to their purchase by members of the unions. The union label is used to a great extent in political campaigns when there is the desire to secure the union vote. In certain industries with many unions, there is a combined label which means that all of the unions in that industry have been recognized. In many cases, each of the individual unions have their own label and stamp it on the product to indicate to other unionists that the product which bears the label is union made and should therefore be purchased by them to support the labor movement.

In the use of the label by combined groups, many disputes occur through the fact that the unions supporting the label vary in strength. Unions having little strength are unable to assure protection to the employer of uniform wages and other conditions. Non-union plants doing one or several of the processes and taking in contract work, that is from other plants,

come into existence operating at lower costs than the union shops. Conflict comes over work sent out to these non-union contract shops specializing in one of the processes of manufacture which cannot be done by the union plant at the same cost. The use of the label by the union is another device of the unions to secure a monopoly of manufacturing. It is only partially effective. As a matter of policy it is up to the individual plant to decide whether or not the union label is sufficiently valuable as a trade mark on their product to justify its use.

Arbitration. Voluntary arbitration is a method used in this country to settle issues which cannot be settled through compromise in joint negotiations of the parties involved. In labor cases arbitration is of two kinds: (a) the arbitration of the vitally important questions of wages, hours, and working conditions when new contracts are involved; and (b) the arbitration of questions coming within the scope of a mutually agreed upon contract over which there is a difference of opinion as to interpretation of individual sections. Because of the fact that the settlement of wages or hours and working conditions for a new contract involves fundamentally a test of strength of the two parties for economic advantage, it all depends on the exigency of circumstances whether or not arbitration will be used as a means of settlement. With one side or the other possessing predominant power to take what it wants, arbitration stands in the way of fulfillment. The tendency on the part of any group is to use its economic power to the limit to force its demands. The weak side advocates arbitration because there is usually nothing to lose and something to gain. In such cases, where arbitration is finally agreed to, the battle over the selection of an arbitrator reflects the efforts of each side to capture the mental margin of the arbitrator in the hope that the decision will be in their favor.

Deadlocks are most likely to occur over issues which are involved in the establishment of a new contract. With the old contract terminated, both sides are free to use their economic strength and are very cautious in committing themselves to an agreement which binds them to waive in whole or in part what they respectively conceive as their right of might. If the respective sides are at issue on questions which involve placing their organizations in jeopardy, such as the recognition of the union on the one side or the right of discharge of the employer on the other, there is a remote chance of securing an agreement to arbitrate. If the issues, however, involve only the question of wages, shop practices and the like, and conditions are not abnormal, such as those which occurred during and following the war, arbitration is resorted to as the best device known to secure a settlement. Seasoned leaders on both sides realize the tremendous cost of industrial warfare and after making their various gestures or threats in an endeavor to feel each other out are inclined to choose arbitration as an alternative. Where practicable an arbitration agreement should extend a month or two beyond the termination date of the wage-scale contract; in any case the wage-scale and shop-practice contract should contain as one of its essential parts the agreement to arbitrate any disputes arising over the interpretation and enforcement of the conditions set forth in the contract. The arbitration agreement should set forth the procedure to govern both parties in presenting cases.

Defining the Issue. One of the fundamental requirements in any arbitration proceeding, whether labor or commercial, is to define the issue. This is very important in order to confine the arbitration to the issue as defined. The best procedure is to define the issue in a mutual submission agreement which both parties sign. This mutual submission agreement has the value of definitely confining the arbitrator to the issue submitted and committing both sides to accept the decision as final and binding for the period set forth in the submission. A satisfactory form used in a number of actual arbitration cases is as follows:

Mutual Submission Agreement

Union proposals	Employers' proposals
Wage scale and shop conditions contract:	Wage scale and shop conditions contract:
between	between
and	and

(State respective demands under each caption.)

- | | |
|---------------------------------------|---------------------------------------|
| 1. Duration of contract. | 1. Duration of contract. |
| 2. Wage scales. | 2. Wage scales. |
| 3. Shop rules and working conditions. | 3. Shop rules and working conditions. |

The above statement of issues is the result of conciliation conferences between the authorized representatives of _____ and _____.

The items in dispute are specifically set forth in this submission and these items only are submitted to arbitration for a decision.

It is agreed that the decision made on the items in dispute as set forth in this mutual submission agreement shall be final and binding on the constituent organizations of both parties to this submission for the duration of the new contract. We herewith this _____ day of _____ of _____ affix our signatures in agreement to the above submission.

Signed

For the union:

Signed

For the employers' organization:

There are cases in which the unions when endeavoring to avoid arbitration and in order to resort to force or the threat of force have attempted to limit the right of the employer to state his own demands. The employer can in no case concede this point without leading himself into a "heads I win, tails you lose" type of arbitration. This applies with equal force where the employer reverses the situation. Both sides must be left free to state their own demands, no matter how extreme these demands appear to be. It is inviting industrial conflict to do otherwise. The following general principles are suggestive as a guide in safeguarding arbitration for long time use as a method acceptable by both sides to settle issues which may arise from time to time in their relations one with the other:

1. The entering into of an arbitration agreement to arbitrate wage contracts is a matter for consideration and mutual agreement by the parties at interest.

2. The constitutional laws covering the internal government of each organization should be understood as exempt from arbitration.

3. The arbitration agreement should be entered into as a part of the contract for wages and should provide arbitration both of current cases arising under the contract and, if at all possible, the basis for arbitrating new contract conditions which cannot be agreed upon in negotiations.

4. The date of termination of any arbitration agreement must be definitely fixed so that at the date of termination both parties will be free agents to enter into another agreement or refrain therefrom.

5. The arbitration agreement should contain a clear and complete code of procedure.

6. The issues in arbitration should be clearly defined and a mutual submission signed by both parties stipulating that the arbitration is confined to those issues and neither party is bound if the arbitration decides issues not submitted.

7. The right of each side to state its own demands must be maintained.

Selecting the Arbitrator. The selection of an arbitrator to decide issues arising over the interpretation of contract clauses already agreed upon involves inherently less difficulty than the selection of an arbitrator to decide the conditions to be incorporated in a new contract.

After arbitration is agreed to as a method of settling the controversy involved, the two parties at issue usually proceed to exchange a list of names. The first list submitted represents possible arbitrators who are distinctly partisan for one side or the other. Each side agrees that if any name on either list is objected to by either side, the name is thereby, without further reason, rejected. As other lists are suggested the tendency is to get nearer and nearer to the impartial type of arbitrator who will be trusted by both sides to make a fair decision. When the list narrows down to a few names through the process of elimination, sometimes these names are placed in a hat and one taken out at random with an agreement by both sides to abide by the result. Another method is for each side to select respectively one man and have the two select the third. There is no absolute rule which can be laid down to settle all deadlocks. In the end one side or the other, no matter what method is used, has, from its point of view, to give in. All that can be done is to narrow down the choice through the exchange of names to someone who is considered reasonably impartial and fair, and gamble on the result.

Preparing the Brief. Unlike legal cases in which there are established precedents which are recorded and to which reference can be made for decisions on the law in point, labor arbitration cases arise out of a complex of dynamic economic forces which mean in each case a new combination. Each side uses what material there is immediately available to prove its case. The procedure is usually for each side to draft a *prima facie* brief, setting forth the basis for its respective contentions. These briefs are submitted to the arbitrator at a hearing arranged for the purpose and the complainant or plaintiff in the case proceeds first to read the brief to the arbitrator without interruption except by the arbitrator. The defendant then in turn reads his

brief and copies are exchanged between the two parties. The arbitrator is given a copy of each brief. If either brief includes statements which the other side desires to check and then submit a rebuttal brief, that privilege is accorded and a second meeting arranged for the rebuttal and sur-rebuttal. There are closing arguments by both sides summarizing their cases and the matter is then left in the hands of the arbitrator to decide.

The brief is usually made up of the following essential parts:

1. A description of the parties involved, whom they represent, the number of people affected by the decision.
2. A short background history of the case and the events leading up to arbitration.
3. A statement of the issue or issues with reference to the mutual submission agreement jointly signed.
4. A list of the points which are important in the case and which are by evidence to be proved.
5. A submission of the factual evidence with exhibits and references or witnesses.
6. Argument, based upon the evidence submitted, showing the reasons why the case should be decided in favor of the party submitting the brief.
7. An appendix of exhibits.

Arbitration hearings do not follow strict rules of evidence but rather endeavor to bring out in open hearings the various points each side has to present until each is satisfied it has had its full say. This procedure permits the submission of material which would not be allowed under rules of evidence. It has, however, the obvious advantage of giving each side the opportunity to the limit to state its case.

Permanent Boards of Arbitration. The method of selecting an arbitrator or board of arbitrators for each particular case when it arises has certain disadvantages. Among them are (1) the inherent difficulties involved in finding a mutually agreed-upon board of arbitrators; (2) each new arbitrator or board selected has to be familiarized with the particular industry and the issues involved; and, (3) decisions made by such changing arbitrators or boards lack continuity. These realized disadvantages have caused some industries to set up what are termed permanent boards selected when controversy is not at its height and available when needed. The set-up of these boards varies, but they usually include one or two representatives from each side with a neutral umpire. Permanent boards set up to overcome certain disadvantages in the temporary boards, have developed certain disadvantages in themselves. Among them are: (1) the industry, instead of placing responsibility on the joint conference committees, made up of leaders on both sides, to conciliate and arrive, if possible, at a decision, is inclined to follow the line of least resistance and load up the permanent arbitrator or board of arbitration with cases involving minor issues; (2) the possibility of the permanent board being discredited because of decisions objectionable to one side or the other; (3) the difficulty of finding men not directly engaged in the industry who will give of their time to the constant adjudication of cases; (4) the danger of, centralization eventually, of too much power in one man or the board.

Both set-ups have merit and are respectively to be adapted to meet the needs of the particular industry for which they are best suited.

Whatever the set-up, the plan should be simple and direct. Experience has indicated that in the long run the definite set-up of permanent joint conference committees made up from representatives of the union involved and the employers who are actively engaged at the trade, has its roots deeper in the industry than permanent boards of arbitration set up with outside representatives and a jointly paid arbitrator. The two plans may be compared through a comparison of the plans in operation respectively in the printing industry and in the clothing industry.

In Canada and Australia the set up of permanent boards is governmental and arbitration is compulsory. Anyone interested in the procedure of these compulsory governmental tribunals and the results obtained can easily secure references covering this subject.

CHAPTER XII

EMPLOYEE REPRESENTATION

BY EDWARD S. COWDRICK

Definition and Classification. The term "employee representation" ordinarily is applied to any method of collective dealing between the management of a company and representatives elected by the employees from among their own number. Mass meetings of employees or occasional negotiation between the management and delegates selected to discuss specific subjects do not constitute employee representation in the proper sense of the term. Union-management cooperation, although it resembles employee representation and in some borderline cases is almost indistinguishable from it, is not treated in this chapter; it is discussed in Chapter XI on the subject Collective Bargaining with Unions. Some of the suggestions here given, however, are applicable equally to employee representation and to union-management cooperation.

Types of Representation Plans. Plans of employee representation show wide variations in the machinery of negotiation which they set up, in the methods of administration, and in the purposes of employers and employees. Structurally, nearly all existing plans fall within one or the other of two groups:

1. The governmental type, in which the organization resembles that of the United States government, with a senate, a house of representatives, and sometimes a cabinet.
2. The works-council type, in which the governmental machinery is lacking and in which negotiations are conducted mostly through joint conferences and joint committees.

A number of plans in the works-council classification belong to a subgroup which might be designated as the employees' association type. Under these plans the employees of a company, plant, or department are organized in an association which functions for representation and sometimes for social and other purposes. Occasionally the officers of the association serve as employee representatives.

Most of the existing plans of representation, especially in the larger companies, belong to the works council rather than to the governmental type. The term "works council" usually is applied to a joint body composed of all of the elected representatives and an equal or smaller number of appointed representatives of the management. The terms "joint conference" or "general conference" are usually synonymous with works council. Some-

times the employee representatives have a separate organization which meets without the presence of company officials.

Subordinate to the works council or joint conference, there may be a number of standing committees, each having jurisdiction over one subject or a closely related group of subjects. Sometimes these committees are composed wholly of elected representatives; more often they are jointly constituted.

Decision as to Desirability of Employee Representation. A manager contemplating the adoption of a representation plan should first of all determine whether or not representation of the employees in his company is desirable. He should not propose it simply because it has been a success in some other organization. He should consider the purposes of employee representation and determine whether or not these purposes conform to the desires of the management in his company.

Employee representation, in a plan properly prepared and adopted, and administered intelligently and in good faith by employees and management, may be expected to attain these objectives:

1. Provide a double-track channel of communication between management and employees.
2. Furnish machinery for the equitable adjustment of grievances.
3. Serve as a means for collective negotiation on wages, hours and working conditions.
4. Educate employees and officials and help each to understand the viewpoint of the others.
5. Provide means for constructive cooperation in the fields of safety, efficiency, and economy.

If the management of a particular company wishes to gain these ends, a plan of employee representation may be the best means of doing so, always assuming that the labor situation is auspicious for adoption of a new method of collective dealing and that the attitudes of employees and officials are favorable. Preferably, representation should be proposed during a time of labor tranquillity. A plan launched in a last minute effort to avert a strike, or to anticipate a unionization campaign, runs grave risks of failure. To the manager who contemplates the adoption of employee representation as a means of "putting something over" on his employees, or who is unwilling to deal fairly and frankly with representatives, the best possible advice is "Don't!" For his type of management any other method of collective dealing, or none at all, will prove more suitable.

Preparation and Adoption of Plan. In a few companies employee representation has been adopted at the request of the workers themselves. This is a desirable initiation, but one scarcely to be expected in ordinary circumstances. Usually management has to make the first move. Even so, it is well to enlist the cooperation of employees at an early stage in the negotiations. In some companies plans have been prepared by joint committees representing employees and management. In others, plans originally prepared by the management have been submitted to a vote of the employees before their adoption. The extent of employee participation at this initial stage will depend upon the circumstances of a particular company.

In any case the plan should be thoroughly "sold" to foremen, superintendents, and other line executives before it is put into effect. The cooperation of these officials is almost indispensable to the success of the project, and this cooperation will be secured with difficulty, if at all, if they are ignored in the adoption of a new labor policy. Foremen once enlisted in support of representation may sometimes be entrusted with the task of explaining the plan and the purposes of the management to the employees in their departments.

Terms of Representation Plan. In deciding upon the precise terms of a representation plan it is advisable, especially if the management has had no previous experience with this form of collective dealing, to make an extensive survey of successful plans in effect in other companies. These plans will be found to present almost infinite variety. Final decision on each point should be based upon the needs and the circumstances of the particular company for which the plan is being prepared.

In some companies, representation has been introduced with extremely simple plans, containing only the absolutely necessary provisions, and detailed rules and procedures have been developed later through processes of evolution. Generally, however, it is considered better to have the constitution of the representative system prepared in full before the plan is put into operation.

Basis of Representation. It is usual to provide for a numerical basis of representation, depending partly upon the size of the plant. One representative for from 10 to 50 workers in a small shop or one representative for 100 to 300 or more workers in a large factory are typical. Usually it is best to arrange voting districts in such a way that each representative shall serve a group of workers with whom he is acquainted and with whose duties he is familiar.

Elections. Elections usually are held annually, sometimes with an overlapping arrangement under which only half the representatives retire at each election. Generally representatives are eligible to be reelected for an indefinite number of terms. A few plans provide for very frequent elections—once in six months or once in three months—but generally this is not desirable. Elections should be by secret ballot, preferably conducted by the employees themselves or jointly by employees and management. Officials may properly urge employees to participate but they should scrupulously avoid any appearance of influencing the vote. In many companies separate votes are taken for nomination and election and this usually is considered good practice, especially in large plants where the employee is likely not to be well acquainted with all the men in his voting district. Voting should be on company time. Efforts to get employees to attend meetings for election, outside working hours, have not usually been successful.

Joint Conferences. In most plans of employee representation the basic element is the joint conference, made up of all the employee representatives elected from the plant or unit concerned and an equal or smaller number of appointed representatives of management. This joint conference usually is the reservoir for whatever authority over the company management is granted to the employees. It serves as a deliberative body and as a forum for the discussion of any subjects of mutual interest that may be suggested by employees or management.

Votes in joint conferences usually are on an individual basis, a majority of the entire number of delegates being required for a decision. In a few plans, however, systems of unit voting are in effect and the representatives of employees and of management caucus separately to determine which way the vote of each side shall be cast. The system of individual voting is preferable, since it makes it easier to avoid sharp issues between employees and management. As a matter of fact, in most of the successful representation plans, the frequency and the importance of voting in conferences have steadily declined and most questions are settled by integration or compromise or by general consent.

In a few representation plans general joint conferences have mainly or wholly disappeared and the largest meetings include representatives of single sections or departments. Some plans provide for separate meetings of employee representatives with no officials present. There are numerous other variations of the joint conference idea. In most circumstances it is preferable to retain the general joint conference and to build up its prestige.

Conducting Conferences. Much of the success of a representation plan will depend upon the skill with which conferences are conducted. For this the responsibility ordinarily rests with the management representatives. There is danger that conferences will become routine and perfunctory and that unless the employee representatives present grievances there will be nothing of interest to discuss. Some companies have made special studies of the technique of conducting conferences and have taken much care in instructing conference chairmen in their duties.

Sometimes subjects for discussion are prepared long in advance and are sent out from the central headquarters to the various chairmen for presentation at their conferences. While this practice is open to criticism as tending to rigidity and to the discouragement of individual initiative on the part of the chairmen, there is no doubt that a reasonable amount of leadership in selecting subjects and planning discussion is necessary. Subjects of mutual interest may include the current business situation affecting the company, prospects for orders and for steady work, accident prevention, the promotion of health, and the initiation and management of the various industrial relations plans in effect or proposed in the company.

In conducting a conference it is advisable to give the employee representatives an opportunity first to present complaints or suggestions on behalf of their constituents. Subjects initiated by the management may then be introduced. Full discussion should be encouraged, especially on subjects brought up by the employees. There should be no appearance of stifling free speech. On the other hand, the chairman needs to be on guard against the danger that the conference will degenerate into interminable argument or gossip over some unimportant topic. Success of the conference depends largely upon the chairman, particularly if he is a representative of management, and he should take his duties seriously and make earnest efforts to prepare himself for them.

Committees. Some representation plans provide for executive committees or boards of appeal, to which may be referred important subjects either before or after they are considered in joint conferences. In a large plant

where the works council is of unwieldy size, it is sometimes advisable to call it together only at infrequent intervals, perhaps once in two or three months, and to leave most of the actual work to a small joint executive committee.

Some representation plans provide for the appointment of standing committees, each entrusted with matters related to one subject or to a group of affiliated subjects. Generally these committees are made up of equal numbers of representatives of employees and of management. Sometimes, however, there are committees of elected representatives only.

Standing committees may serve a useful purpose in considering complaints or suggestions and perhaps settling them before they reach the general joint conference. In one company the standing joint committees bear the following titles:

- Joint committee on cooperation, conciliation, and wages.
- Joint committee on safety and accidents.
- Joint committee on sanitation, health, and housing.
- Joint committee on recreation and education.

In some companies joint committees or committees of employee representatives conduct elections and have charge of the organization of each new joint conference. It is good practice to have joint standing committees report at each joint conference meeting. Some representation plans require a written annual report from each committee, outlining its work for the entire year.

Salaried Employees and Representation. Foremen generally are considered representatives of management and sit in that capacity, if at all, in joint conferences and joint committees. A few companies have experimented with separate representation plans for foremen and in some others wage earners are permitted to elect foremen to represent them. Neither practice is desirable.

There has been some difference of opinion as to whether office workers and other salaried employees of non-supervisory grade should be included along with wage earners in a representation plan. Generally it will be found better to exclude these employees, on the theory that they are potentially, if not actually, a part of the management. This rule should perhaps be modified, however, in companies where large numbers of clerical or other salaried employees actually make up a considerable portion of the rank and file. In some public utility companies, for example, a plan which did not include office employees would scarcely be representative of the working force.

Adjustments and Appeals. An essential function of representation is the settlement of grievances and the adjustment of disputes between employees and management. Companies have handled this function by different methods and with different degrees of success. Unwillingness to deal fairly with employees or lack of intelligence in administering a representation plan is likely to result in interminable wrangling, with consequent suspicion and ill will on both sides.

In adopting a representation plan, the management should make up its mind just how much authority it is willing to delegate to employees or to joint conferences or committees. Precedent can be found for almost any

variation, from purely advisory committees at one end of the scale to "management by town meeting" at the other. It is significant that the success of a representation plan or the degree of confidence which it inspires among the working forces seems to have little connection with the amount of authority granted to the representatives. Of the plans which have had outstanding success some are amply provided with "teeth," while others grant to the employees little or no authority in matters of management. Another significant fact is that in some companies, the terms of whose representation plans give wide powers to the representatives, these powers are seldom exercised.

One may safely conclude that under typical conditions a works council, whatever the terms of its constitution, functions less as a judiciary body for the formal adjustment of controversies than it does as a discussion group in which misunderstandings are cleared up and differences of opinion settled informally through compromise or integration.

It should be remembered also that few if any representation plans are designed to bring about "industrial democracy" or to turn the management of the business over to the wage earners. Usually the wage earners have no desire to manage the business. What they want is a reasonable degree of control over things that concern themselves—notably wages and working conditions. There is room for argument as to what constitutes a reasonable degree of control, but whatever may be the verdict on that point, there seems to be little doubt, in the light of experience, that the workers can influence shop conditions about as effectively under an advisory plan as under one that ostensibly provides for actual sharing of management responsibilities. The fairness of both sides, and their willingness to cooperate and compromise and to see things from each others' viewpoints, are the really vital elements.

Settlement of Grievances. In the adjustment of personal grievances, it is good practice to insist that the foreman directly concerned be given an opportunity to satisfy a complaining employee before a case is taken over his head to higher executives or to a joint committee or joint conference. It is preferable to have the individual employee with a grievance take it up with his foreman before even consulting his employee representative, but this should not be insisted upon, since there may be valid reasons why the employee hesitates to approach his foreman without support. Some employee representatives adjust many complaints informally, either by talking them over with the foremen concerned or by showing the complainants that their cases are without justification.

One factor by which to judge the successful administration of a representation plan, is the proportion of grievances that are satisfactorily adjusted in the departments in which they arise, without the necessity of appeal to higher executives or of adjudication in conference or committees. If a foreman fails to make a satisfactory adjustment, however, the way should be left open to appeal the case to the foreman's superiors or to whatever machinery is provided in the representation plan.

As to just where the right of final decision should rest, there is much difference in theory and practice. Some representation plans provide for enforced arbitration or for appeal to an impartial outside body; for example, the U. S.

Department of Labor. Others limit the appeal to the president of the company or the board of directors. In still others there is no provision for further action if the joint conference fails to reach a majority decision, the theory here being that in such a case the machinery of representation has simply failed to function and the rights of each party remain just where they were when the controversy started.

Authority for Discharge. Under almost all representation plans, a complaint that an employee has been unjustly discharged is an individual grievance, which may be adjusted by whatever machinery is provided. The plans of a few companies include specific lists of offenses for which, and only for which, an employee is liable to discharge without notice. Under this kind of an arrangement the only question that logically could be taken up through the representation plan is as to whether or not the offense was actually committed. In some companies foremen and employment managers make a practice of consulting employee representatives in advance before discharging a workman. This is a desirable method, since under modern systems of employment and discipline there are relatively few discharges for cause and those few are readily explainable.

Representation and Wage Setting. Under practically every representation plan wage rates are open to discussion in conferences and committees and a complaint regarding wages has the same standing as any other grievance. With this generalization, however, similarity among the practices of different companies ends. Examples may be found of almost every possible relationship between wage setting and representation. Some companies agree that general changes in wage levels shall be made only with the consent of the employee representatives. Others consult the representatives in advance before setting new rates. In still others employee representatives participate in time studies. In many companies, however, rate setting is wholly divorced from the representation system—perhaps also from the industrial relations department—and the only function of employee representatives is that of protest against alleged inequities.

In times of business depression or falling commodity prices, some companies have successfully negotiated wage reductions with the employee representatives. Other managements, however, believe that this procedure is wrong in both theory and practice and that it is unfair to ask representatives of the wage earners to consent to reductions in pay.

On this whole subject it would be difficult to lay down a rule applicable to the conditions of all companies. Certainly the management should be willing freely to discuss wage questions and should take every proper opportunity to explain to the employee representatives the basis of wage determination and the methods by which rates are set. There should be no attempt to shut off wage discussion or to prevent employees and their representatives bringing up wage complaints. Beyond these general principles the exact relationship between wage setting and representation can best be determined by each company in view of its own conditions.

Problems of Multiplant Companies. Special problems arise when a corporation has several plants or operates through subsidiary companies. Present-day industrial philosophy inclines to the policy of giving the plant

manager wide authority over industrial relations and other local operating problems. At the same time it is generally recognized that labor management, at least in its broader principles, should be uniform throughout a corporate organization. In some companies employee representation has been adopted on the initiative of the top management and the plans at various plants are similar, if not actually uniform. In others, particularly where representation has been initiated at the separate plants, wide variation is found in the different plans and in the methods by which they are administered.

Under normal conditions it is preferable to have company-wide agreement, at least on the general principles of the representation system, and to modify these principles in practice only to the extent that differing local situations make variations desirable.

Meetings of Representatives from Different Plants. In some companies representation plans provide for general meetings attended by representatives from all plants, even though these units may be widely separated geographically. In others the largest representation unit is the separate plant and no provision is made for contact between representatives of more than one mine, factory, or office. Various compromises are made between these two extremes, as, for example, when conferences are attended by representatives from all the plants in a given geographical area or from all the operations of one subsidiary company.

The weight of present-day thought seems to incline toward the limitation of representation activities to the single plant, although the general officers of a company usually maintain contacts with representatives of various plants and appeals generally can be taken beyond the local manager.

Executive Contacts. If any one thing is essential to the success of employee representation it is the continuous interest and cooperation of the company management. No representation plan is good enough to run itself. No mistake is more disastrous than that of believing that a representation plan, once adopted and set in motion, will operate automatically to adjust industrial relations.

Functions of Higher Executives. Support of the representation plan should start at the top. If the president of a company is too important a man to take an interest in representation, that company probably will get along better under some other form of labor management. The president should have—and has under most representation plans—a place in the line of appeals open to the employee with an unsatisfied grievance. It is desirable to have him meet the employee representatives at least occasionally. In some companies the president attends one joint conference at each plant every year and addresses the delegates on business conditions or other subjects of mutual interest.

The highest operating executive of a department in which representation is in effect—for example, the general manager or the vice president in charge of manufacturing—ought to maintain an active relationship to the representation plan, attend meetings when possible, confer with representatives on suitable occasions, and in general assume the responsibility for the administration of the plan.

Naturally much of this responsibility will be delegated to plant managers. These officials should attend most of the works conferences at their plants; confer frequently with the representatives; hear cases on appeal; announce company decisions, and explain company business conditions. In the ordinary routine of labor administration the plant manager usually is the highest executive who has frequent dealings with the representatives and will naturally be looked upon as the spokesman for the company management. This, however, does not relieve the general officers of the company of their responsibilities in connection with the representation plan.

Functions of Superintendents and Foremen. Department superintendents, general foremen, foremen, and subforemen should cooperate in the administration of representation in the departments or shops under their jurisdiction. To these officials falls much of the responsibility for day-to-day negotiation with employees and representatives over suggestions, grievances, and other matters related to the routine of the shop. Some superintendents, and even some foremen, make a practice of holding regular departmental or shop conferences with representatives of the men under their jurisdiction. Conferences of this kind may be of great value both to management and to employees.

Under the most approved practice employees or their representatives are required to take up complaints with the foremen directly concerned before appealing them to higher officers or seeking satisfaction in joint conferences or joint committees. Thus a foreman is always given the first opportunity to adjust a complaint.

With successful operation of the representation plan it usually is found that a continuously increasing proportion of all complaints are settled in the shops where they arise. This policy, however, should not be pushed to the extreme of allowing a foreman to make a decision, right or wrong, and be sure of support from his superiors. The old notion that discipline could only be maintained by invariably backing up the foreman or the superintendent has been discarded in companies that have modern labor policies.

Some foremen have found employee representatives distinct assets to them in managing their shops. By cooperating with these representatives and explaining company policies to them the foremen have secured their support and assistance in handling disciplinary cases and relaying information to the rank and file of the working force.

Foremen and superintendents often serve as management representatives in joint committees and joint conferences. A few companies hesitate to appoint first line supervisors to these positions, on the ground that employee representatives will not talk freely in the presence of their immediate superiors. Majority experience, however, does not support this theory. In most companies it has been found advantageous to gear the foreman directly and actively to the representation machinery.

Whatever may be the exact functions assigned to foremen and superintendents, there is no question that the cooperation and support of these line officials is essential to the full success of representation. Some of the earlier representation plans were put into effect with little regard to the opinions and prejudices of the first- and second-line supervision. The thing that

looked important was to establish direct connections between the top executives and the rank and file of the workers. The result was friction and misunderstanding, with perfunctory support or none at all by the foremen and superintendents. With better understanding of labor management and industrial psychology, managers now make earnest efforts to enlist the support of the line officials before launching representation plans or other innovations of labor policy.

In one company that has had outstanding success in administering representation the manager of industrial relations always visits a plant before a representation plan is installed and spends two or three weeks, if necessary, in explaining the idea to foremen and superintendents, answering their questions and objections and making sure that they are in accord with the labor policies of the management. It is important also to secure the support of inspectors, time-study men, safety engineers, and others whose duties bring them into direct contact with labor.

Functions of Personnel Department. Almost always the routine administration of a representation plan is a responsibility of the local or general industrial relations department of the company. Within the plant the personnel director usually arranges meetings, confers with representatives, and takes responsibility for following up suggestions and complaints and making sure that decisions are rendered and transmitted promptly. Sometimes he serves as chairman or secretary of some or all of the joint bodies constituted under the plan. He may have a place in the line of appeal open to an unsatisfied complainant or he may represent the plant manager in hearing cases on appeal. Nearly always he finds it necessary to prompt the operating officials, explain their functions under the representation plan, and make sure that these functions are not overlooked in the press for production. Likewise he generally has to instruct the employee representatives, guide them in carrying out their duties, and interpret to them the policies and decisions of the management. Often he finds it advantageous to prepare programs for committee and conference meetings, select officials to address the representatives, assign their topics, and sometimes write their speeches.

The degree of prominence which the local personnel man will assume in the administration of the representation plan will depend largely upon his personality and upon the personalities and ideas of the executives to whom he reports. In some plants the industrial relations director functions as the mouthpiece of the company and serves as the principal point of contact between employees and management. In others he remains in the background, works behind the scenes, and secures results just as effectively as if he were always in the center of the stage.

In a company having several plants there is usually a central industrial relations department serving the managing executives in a staff capacity. This industrial relations department usually maintains a general advisory supervision over the representation plan, follows up complaints that are not adjusted promptly in the plants in which they arise, and consults with the operating officials on matters of general labor policy. Ordinarily the director of industrial relations visits the different plants, attends conferences as often as convenient, and confers with representatives, superintendents and foremen.

As administrator and interpreter of all the labor policies of the company, the director of personnel usually has the responsibility for adjusting representation to whatever other plans are in effect, and maintaining harmony between the various parts of the entire industrial relations system. This is a function of prime importance. Employee representation is not the whole of a labor policy. It is only a part of it and needs to operate smoothly and efficiently with all the other parts.

Chairmanship of Conferences and Committees. In some companies the ranking line executive, usually the plant manager, presides at general joint conferences and an official is likely to be chairman of each joint committee. In other companies chairmen elected by and from among the employee representatives serve as presiding officers. In still others, the general or local industrial relations directors preside at meetings. There is no uniformity of usage in this respect; almost every imaginable method of assigning chairmanships may be found working successfully in some company or plant.

Probably the majority opinion inclines toward the chairmanship of the ranking company executive, and usually this arrangement is not resented by the employees. If the plant manager or other high official serves as chairman, however, he needs to guard against assumption of too much authority and the discouragement of free speech on the part of the employees and his subordinates in the official organization. A chairman with official prestige and dominating personality is under constant temptation to "talk down" his opponents and settle questions autocratically. Too much domination by officials is one cause of the indifferent success of some representation plans.

Preparation and Distribution of Reports. Usually the joint conference and each standing committee chooses its own secretary, who is likely to be an employee representative. The principal duty of this secretary is to prepare minutes of meetings and other reports for distribution to employee representatives and officials. Frequently it is advisable for the management to give the elected secretary some assistance, or even to have reports written for him and submitted for his approval and signature. Care should be taken not to ignore or supersede the secretary, especially if he is an employee representative. In every case he should be given an opportunity to read, correct, and sign the minutes before they are distributed.

Minutes should be neither too "sketchy" nor too verbose. Verbatim reports of discussions generally are to be avoided. Debates and decisions should be reported fairly and without appearance of prejudice. Especially if the minutes are prepared by the management, care should be taken to state the employees' side of each case fully and avoid giving the impression that the management always was able to persuade the employees that it was right. On the other hand, the secretary should not unduly cater to the political type of employee representative, who constantly shoves himself forward and seeks to make himself a hero or a martyr.

Much variation is found in the methods of distributing conference and committee minutes. Sometimes these reports are widely disseminated through the plant, posted on bulletin boards and otherwise made available to all the employees. Sometimes they are furnished only to officials or to officials and employee representatives. Sometimes they are published in full in plant magazines or in pamphlets for general distribution.

A fairly wide distribution of at least the minutes of general joint conferences is desirable, since these reports contain, or should contain, most of the information which employees ought to have about the functioning of the representation plan.

Minutes usually are sent to plant and general executives of the company and to local and central personnel departments. This is important as a means of following up complaints, expediting decisions, and maintaining executive supervision over the operation of the plan.

Company Information for Employees. One of the main purposes of representation is to provide a means of furnishing company information to employees. Recent years have seen a striking change in the attitude of management on this point. Formerly much of the vital information relating to company business was looked upon as a sort of sacred mystery, to be discussed only in directors' meetings or at conferences of executives. In some companies this attitude still prevails. Among modern-minded managers, however, there has grown up a constantly increasing tendency to share facts freely with employees, with stockholders, and with the public at large.

This tendency is particularly impressive in the case of employees. Many managers make a practice of discussing freely with employee representatives such intimate topics as costs and earnings, outlook for future business, prospects of steady or irregular work, possibilities of building up or reducing the working force, and all sorts of things that are of mutual interest to the employees and the company. Sometimes cost sheets are taken into joint conferences and explained in detail to representatives and foremen. In a number of companies each annual report is summarized and explained by competent officials who attend conferences for that purpose.

This spreading of company information among the employees may be extremely useful in building up confidence, establishing loyalty, and preventing misunderstandings and the spread of irresponsible gossip. It is such an important element in the administration of a representation plan that it may almost be said that a company which does not wish to make information available quite freely to its employees will be better off without representation.

Naturally it should not be understood that a representation plan is the only method of furnishing company information to employees. Bulletin-board publicity, plant newspapers and magazines, mass meetings, educational conferences, and numerous other devices have been used successfully for the same purpose. It would appear, however, that employee representation, by affording frequent contacts between the officials and selected representatives of the employees, is the best means thus far devised for providing a double-track channel of communication between management and working forces.

Following Up Questions Raised in Conferences. In a large company with several plants and numerous departments, there is need for a close follow-up of the questions raised in joint conferences or committees. This is particularly important in the case of complaints presented by employees. However good may be the intentions of the management, there is danger that some question vitally important at least to the man who raised it will be referred to a committee or a department head and then overlooked until it becomes a cause of

friction and misunderstanding. It is important that decisions of the management should be fair and equitable, but it is almost equally important that they be rendered promptly.

The follow-up of cases arising in a representation plan usually is a duty of the local or company personnel manager. He should receive reports of all meetings and should keep a record of all unfinished cases. If there are indications that an official is unduly delaying decision on a question that has been referred to him, he should be reminded of the case, repeatedly if necessary, and urged to get it cleared up. It is highly undesirable to have a question, especially if raised by employee representatives, reported as unfinished business at repeated meetings of a works council. If the management has a legitimate reason for delaying a decision, this reason should be fully explained to employee representatives.

Selection and Development of Representatives. Types of representatives elected by employees are likely to show as wide a variation as is found among candidates chosen under any other elective system. In almost any works council the elected representatives are likely to include some who are radical and some who are too conservative; some who are belligerent and some who always agree with the management; some who play politics and some who are elected against their will and wish they were not there; some who try to monopolize the center of the stage and some who can rarely be induced to say anything; some who are mentally keen, some who are about up to the intellectual average of the working force, and some who are simply stupid.

In the selection of representatives the management properly can exert little or no influence beyond urging employees to participate in elections and to vote for the men they think will best represent them. To bring managerial pressure to bear for or against a particular candidate threatens the integrity of the whole representation plan and is almost certain to destroy employee confidence.

However, the management can, and properly may, instruct the elected representatives in their duties and seek to develop their capacity to perform them. In some plants the personnel manager confers with all newly elected representatives, explains the representation plan and their rights and duties under it, and tries to get them started on the job with an adequate understanding of what it is all about. In other companies the first joint conference after an election is taken up largely with a discussion of the representation plan and the instruction of both employee and management representatives in their duties. Handbooks of information sometimes are used for a similar purpose.

Many representation agreements contain guarantees that employee representatives shall not suffer discrimination on account of their activities in behalf of their fellow workers. This immunity, whether or not it is written into the representation plan, should be scrupulously protected. There is no greater farce than a works council in which the elected delegates are afraid to talk freely lest they "get in bad" with the management. Wise managers generally have leaned over backward in permitting the utmost freedom of speech. One company president's statement in a joint conference that "nobody's going to get fired for shooting off his mouth," is rather character-

istic of the attitude of forward-looking executives. The writer recalls one representative whose queries and retorts to the highest officers of the company sometimes became positive insults. He held his job, retained the respect of the management, and ultimately was made personnel director of a large factory.

There is danger, however, that some officials, especially in the subordinate ranks, will try to make things disagreeable for representatives who become too zealous in promoting causes that are displeasing to the management. This danger should be guarded against at whatever cost. Evidence, or even well-grounded suspicion, that activity on the part of a representative militates against his standing in the shop is sufficient to nullify any good results that otherwise might be gained through representation.

Radicals and Conservatives. Among a body of workingmen there is likely to be a sprinkling of radicals who look with disfavor upon the existing economic order and who are suspicious of everything originating with the employer. Men of this type, if they happen to have the elements of popularity, are likely to be elected to the works council. Often that is the best place for them. In employee relationships, as in politics, the best treatment for a radical is likely to be that of putting him in a position of responsibility. The history of employee representation contains numerous instances of radicals and "trouble makers" who have developed into the most reasonable and most intelligent of employee representatives. It is only fair to add that there are some other instances in which radicals have proven to be insincere and throughout their careers as representatives have played to the gallery and attempted to take unfair advantage of their positions. The latter class, however, are in the minority.

Dealing with a radical representative, especially in the early stages of his service, calls for tact and good judgment on the part of the manager. Usually this representative is intelligent but inadequately informed. If he shows indications of honesty and sincerity, it is worth while to take whatever time is necessary in presenting the facts and explaining the company's point of view. If he wants to talk in meetings he should not be shut off—at least not until it has been demonstrated that he is playing politics. Often it is well to appoint him to important places on committees and to entrust him with difficult duties in order that he may get a taste of responsibility.

Perhaps even more difficult to deal with than the radical is the representative who is too compliant, who always agrees with the management, and who never is willing to make a fight in behalf of his constituents. This representative is likely to serve only one term. During that term the manager should seek to stiffen his backbone and to show him that he was elected really to represent his fellow workers. A representative who is merely a "yes" man for the management is as useless to the company as he is to his constituents.

Women as Representatives. Most plans permit the election of women as representatives, and some of them prescribe a definite apportionment of representation between men and women employees. In shops where the majority of the employees are women, and where freedom of choice is unrestricted, most of the elected delegates may be women—or, on the other hand, they may not. Feminine psychology in the factory is no less baffling, from the

viewpoint of the masculine observer, than it is anywhere else. One group of women workers may elect as their representative one of their own number who has natural traits of leadership and all the qualifications for effective service. A similar group may persist in choosing any man who happens to be available, however much his ability and temperament may unfit him for the position.

Women representatives have served in works councils with varying degrees of success. A few have been conspicuous leaders, looked up to by wage earners of both sexes. Some have been indifferent and disinterested. Perhaps the majority sitting in mixed assemblages have been unduly inclined to take the back seats and to yield to their masculine colleagues the places of leadership in representing the working forces. It is to be expected that the skill of women representatives, and the value of their services to their fellow employees, will improve with experience. Certainly their selection should be encouraged in shops where the majority of the workers are women.

Promotion of Representatives. An important by-product of employee representation is the uncovering of raw material for supervisory and executive positions. In some companies a large proportion of the foremen have served as employee representatives before their promotion from the ranks. Often a worker has qualities of leadership which would be discovered late, or not at all, except for the opportunities presented through the works council. Naturally experience as an employee representative is valuable to the worker who later is elevated to supervisory rank.

In selecting men for promotion, the management should avoid discrimination, either favorable or unfavorable, toward employee representatives. There should be no appearance of getting rid of a troublesome representative, or buying his favor, by advancing him to a foremanship. On the other hand, service in the works council should not prevent or delay a worker's promotion.

For the worker who has qualities of leadership, but who lacks training, experience, or some other element requisite for a supervisory position, representation often provides an outlet and an opportunity for service. Sometimes an employee representative of this type is a powerful harmonizing influence, and accomplishes more in promoting satisfactory industrial relations than almost anyone else in the factory.

Full-time Representatives. Occasionally, either by the terms of a representation plan or through local custom, the employees of a factory or a department have a full-time representative, who does no manual labor and who devotes all his attention to representation duties. Usually a representative of this kind is paid by the company and receives compensation approximately equal to what he would earn at his regular occupation. While occasional instances may be cited in which these representatives function usefully and without cause for criticism, the practice generally is not to be encouraged, and its justification in a particular company requires affirmative evidence that there is need for a full-time spokesman for the working force.

Constructive Cooperation. Employee representation originated largely as a method of securing justice and preventing friction between employers and employees. That purpose is still vital and should by no means be overlooked. In recent years, however, it has been found that the adjustment of grievances

and the elimination of misunderstanding is only a part of the service which may be rendered by a representation plan. There is a whole field of constructive cooperation on such subjects as efficiency, economy, elimination of waste, accident prevention, and the promotion of company prosperity. Some companies which have taken full advantage of the opportunities in this field have achieved results of outstanding value.

In the early stages of nearly every representation plan conferences and committee meetings are taken up largely with the presentation, discussion and adjustment of grievances. Usually there is a dammed-up reservoir of complaints which descends in a flood as soon as representation provides the opportunity. As time passes, however, these accumulated grievances are adjusted and new ones are taken care of currently, usually by the foremen. Eventually a stage is reached at which seemingly there is little for the representatives to do.

This stage marks a critical period in the development of representation. There is danger that meetings will become routine and perfunctory and that employees and officials will lose interest. One or two companies have even reported that their representation plans were abandoned because there were no grievances and therefore nothing for the conferences to do.

It is at this point that the efforts of the representatives may be turned into constructive channels. The initiative generally must be taken by the management, but in most cases the employees will be found interested and receptive. A waste elimination campaign, for example, may be put on through cooperation of representatives and foremen. Joint committees may be appointed to inspect products for quality or to promote safe working practices. There is no limit to the fields that may be entered—and actually have been entered by some companies—in this type of constructive cooperation.

Periodic Audit of Results. In everything that has been written in this chapter stress has been laid upon the importance of executive supervision. It has been brought out repeatedly that a representation plan will not run itself and that it needs constant guidance by responsible officials. It remains to be added that the effectiveness of this guidance and the degree of success that is being secured may be determined through periodic audits of the representation plan. These audits may be made either by company officials—for example, directors of industrial relations—or by outside consultants in whom the management has confidence.

An audit preferably should be made at least once a year. It should be conducted so as to determine what were the original objectives in introducing the representation plan and to what extent, if at all, these objectives have been modified; to what degree the objectives are being attained; what, if any, unexpected results, good or bad, have grown out of representation; whether the number of grievances is increasing or decreasing, whether any grievances remain unadjusted, and what proportion of them are settled by the foremen at the points of origin; whether representation is gaining or losing the confidence of employees, foremen and executives; whether decisions are given fairly and promptly by officials and joint committees; what type of employees are elected as representatives and whether this type is improving

or deteriorating; what changes in the plan or in its administration would be desirable in the light of experience.

The results of each audit should be carefully checked up by the personnel organization and brought to the attention of the responsible company executives. Errors or abuses that are disclosed should be corrected promptly. Suggestions for changes or improvements should be given adequate consideration, and adopted if they seem practicable and desirable. By this means the company management can do much to keep its representation system functioning with maximum efficiency and usefulness.

CHAPTER XIII

LABOR LAW IN THE UNITED STATES¹

By GLENN A. BOWERS, *Industrial Relations Counselors, Inc.*

Labor law in the United States, both statutory and common law, manifests itself in the acts of the legislatures, the rulings of the courts, and in the conduct of executives and the administrative units created by Congress and state legislatures. The keystone of this group is the legislature responsive to the people. When substantial sections of the people want to establish a standard, or get protection or preference which cannot be achieved through their own efforts, a demand arises for a law. If the demand is reasonable and particularly if it is supported by a potential block of voters, a new statute is enacted. Thousands of such enactments have come from Congress and the state legislatures principally during the past sixty years, and each year several hundred bills are up for consideration.

Numerous as are the labor laws, they cannot, however, set down specific rules for all issues which may arise in industrial relations. Cases come into court for which there is no direct precedent or in which newly developed circumstances require variation from previous rulings. The court, unable to wait for the instructions of the legislature through a new law, may be forced to fill in a gap in the law in making its decision. Thus the cry against judge-made law is raised. This is a particularly characteristic reaction to the granting of injunctions in labor disputes.

Finally the labor departments, factory inspection services, accident compensation boards, and other related administrative agencies are vital factors in the law of industrial relations. Their importance rests upon their responsibility for law enforcement. Weakness in these departments tends to nullify the statutes and thwart the will of the people as expressed by the legislatures.

Kinds of Labor Laws. There are broadly three kinds of labor laws; those which restrict or forbid, those which require, and those which permit a practice or condition. In the first category are laws which restrict immigration, child labor, hours of work, and prohibit the use of poisonous materials. The second class includes laws requiring the safeguarding of equipment, the maintenance of sanitary conditions; those specifying the method and medium of wage payment; and other measures for the physical protection of the worker. The third group of laws extend the privilege of choice, such as laws providing for voluntary arbitration, the incorporation of trade unions, and for the formation

¹ This is a major extract from a paper presented at The Institute of Public Affairs, University of Virginia, Aug. 6, 1930.

of benefit associations, labor unions, and cooperatives. Many labor laws cross the boundaries of this classification. It may be said that all compulsory laws permit the choice of refusing to operate at all under the conditions laid down, or that all restrictive laws are prohibitions to some extent.

A more useful classification would seem to be one which makes a distinction in the subject matter of the legislation. Thus, the labor market, the employment contract, working conditions, and collective bargaining constitute the main divisions, although enactments for the special interest of selected groups and for the broad general interest of all working people must be included to complete the picture.

The Labor Market. The earliest of laws relating to the labor market—unless the slave trade laws be included in this category—were probably those of the early sixties restricting the system of contract labor, prohibiting coolie trade, and legalizing, under a brief-term Federal Statute (1864 to 1868) the importation of indentured servants. Beginning with the Act of 1882, subsequent laws were enacted further to restrict immigration by excluding certain classes of undesirables, these culminating in the quota limitation acts of 1921 and 1924.

Other legislation affecting labor supply includes that which regulates the use of prison labor, limits hours of work, and forbids women and children to work at certain occupations or at night work. Laws relating to women and children, however, are usually referred to in connection with restrictions to the labor contract rather than with the supply of labor.

In the present century there has been added to this group of laws on the labor market statutes which provide for public employment bureaus, both state and Federal. There are some 250 public employment offices in the United States today.

The Employment Contract. Public regulation of the employment contract involves issues which are more controversial than the limitation or adjustment of labor supply. Here one encounters the *limitation of hours and working periods*, the *fixing of minimum wage rates*, and *compensation for employment hazards*. In exercising or attempting to exercise control over these terms of employment, public authority runs directly into the principle of individual liberty. Freedom of contract has been looked upon as a fundamental right and so it is as a general principle. A superior interest—the well-being of the public—may, however, make itself felt through the exercise of the police power. It is on this ground that the legislatures have in a large number of cases interfered with the general rights of employers and workers to agree upon the terms of their relationship. Were it not for certain constitutional safeguards, however, the continued application and extension of the police power would eventually result in dominant state control of employment relations, for in this field it has often been reasoned that the public interest is primary. These safeguards in the Constitution place a check upon the use of the police power and thus permit of a method other than state control to attain the elusive social welfare. Freedom of contract, while concededly subject to certain restrictions under the police power, is yet preserved by judicial interpretation of constitutional rights of the person and of property. By applying the rule of reasonableness to questionable statutes, the courts

slowly but surely reflect the changing requirements and public attitudes of our industrial order. Thus the Supreme Court of the land has endorsed the constitutionality of a law which fixes the maximum hours of a working day for all persons in mills, factories, and manufacturing establishments. Twenty-seven states now have such laws applying generally to manufacturing industries or to special industries or occupations. Every state has laws limiting hours of work for children under sixteen years, and all but five states have legislation of this character for women workers.

Other legislative limitations on working periods include Sunday labor, one-day-rest-in-seven, night work for women and children, daily rest periods, and legal holidays. In total this limitation on the work contract is widespread and extensive although of varied application in the several states. It should be noted that the federal Adamson law fixing the eight-hour day for railroad workers rests upon commerce powers rather than on the police power.

The second important interference with the employment contract is that group of laws which *specify conditions of wage payment* or fix minimum wage rates. State regulation of the time of payment, medium of payment, payroll deductions, and security of payment of wages has become so common and generally observed, that its existence is often forgotten. On the other hand, minimum wage laws have been applied successfully in the United States only to minors. Some sixteen states, since the passage of the first minimum wage law in Massachusetts in 1912, have adopted laws of this character for women and children. These statutes, however, have been stripped of their compulsory character, as applied to women, by the federal Supreme Court in the case of *Adkins v. Children's Hospital*.

Finally, as regards the employment contract, during the past two decades a trend has developed toward the *compensation of employees for certain hazards of employment*. Such compensations when required by law becomes as definitely a part of the employment contract as an agreement for wages in contemplation of work performance. Accident compensation laws now exist in all but four states: Arkansas, Florida, Mississippi, and South Carolina, in which states employer's liability acts, however, have removed the old common-law employer defenses in suits for damage. A few years ago agitation for state health insurance arose, but quickly subsided in favor of coverage of this hazard by voluntary private insurance developed on a group basis. More recently a demand has arisen for state unemployment insurance, a score of states having considered bills in legislatures. Also since 1915 fifteen states have adopted old age pension laws, but these being in the nature of public outdoor poor relief and not requiring industrial contributions, except through taxes, are not strictly within the field of labor legislation. Nearly all states provide pensions for mothers of needy children. Thus, except for an almost universal prevalence of compulsory accident compensation, the movement in the United States for state social insurance does not yet have an incidence directly upon industry.

Working Conditions. Working conditions, the third of the present divisions of labor legislation in the United States, includes statutes requiring safety equipment, those for the prevention of occupational diseases, and for the maintenance of sanitary conditions. The statutory requirements of

safety appliances, fire protection, wash rooms, freedom from poisonous gases and materials are widespread and among all labor legislation are now the most generally endorsed.

Collective Bargaining. Collective bargaining statutes, the fourth division, naturally arouse intense feelings among employer and employee groups. Each new legislative act is bitterly contested and usually carried promptly to the highest courts for interpretation. Both sides have ordinarily wanted the Governmental referee to make as few rules as possible and usually prefer to have the contest between them settled on economic grounds. But occasionally, either side may run to cover and demand special legislative protection as the employers did in a score of states at the end of the World War in urging and securing the adoption of laws against syndicalism and radical doctrines and as the trade unions have been trying to do for many years in advocating laws to curb the use of the injunction in labor disputes.

On the whole, there has been relatively little governmental interference with collective bargaining in industry of this country. Laws protecting the union label exist in the majority of states; blacklisting is forbidden in twenty-four states; picketing is protected under laws of nine states and within Federal jurisdiction but forbidden by statutes of three other states and one territory; interference with employment relations is forbidden in more than half of the states; while sabotage, industrial police and bribery are variously legislated upon. Notwithstanding this array of specialized statutes, the law of collective bargaining is still largely determined by constitutional provisions under interpretation by the courts.

In brief, the federal and state governments under existing interpretations of the Supreme Court of the United States, may not destroy, by statute or otherwise, the basic freedom of the individual worker to contract at will with an employer or vice versa, for to do so would be a violation not only of his liberty, but of his property right. The conditions of work under such contract may under certain circumstances be regulated.

This portion of our labor law that is relative to collective bargaining and joint relationships is especially complicated by the responsibility of the courts to examine in each case the fundamental character of the employer-employee activities involved, or of the contested statute which undertakes to regulate them. Needless to say, there are many points here as in other branches of labor law which yet remain vague and uncertain. It may be that new circumstances will cause even the Supreme Court of the United States to abandon, as it has done in the past, some of its interpretations of constitutional liberties, but one may be assured that such shifts in position will be made slowly where at all.

Compulsory arbitration of labor disputes has not fared well in the United States. In employments vested with a strong public interest, such as railroads and public utilities, there is no question of the constitutionality of legislation requiring it. In the case of the Transportation Act of 1920 so much dissatisfaction developed among the employees and employers affected that the compulsory arbitration feature was withdrawn in favor of a voluntary provision. The Kansas Arbitration Act of 1920 was unconstitutional, insofar as it undertook to bring within its compulsory sections employments which

could not reasonably be regarded as being clothed with public interest. A step in the other direction, however, is taken by the Colorado law of 1921 which provides for compulsory investigation of industrial disputes, and by approval of a federal court, forbids strikes and lockouts pending the decision of the commission. This decision may be rejected by either party. While compulsory arbitration has not been popular, the voluntary services of the state are generally available through commissions or bureaus whose duties include investigation, conciliation, and arbitration of disputes. Thirty-six states and the Federal Government have statutes providing for these services in varying degree and manner.

Protection of Special Groups. Governmental protection of the interests of special groups, such as seamen, railroad employees, government employees, women and children, constitutes the fifth division of our outline of labor laws. The theory underlying this type of legislation is that members of these groups are in certain respects limited in their opportunities for full protection of their own interests by virtue of the nature of their employment, or, in the latter two classes, because of physical characteristics. Children, furthermore, are regarded as wards of the state. Detailed reference need not be made here to the regulations of working conditions for seamen under the La Follette Act of 1915, to the semipublic employment on railroads, nor to the status of government employees, both state and federal. Their unique positions as subject to Governmental regulation is generally acknowledged. Special attention, however, may be directed to the attempts of Congress to adopt federal child labor laws and a minimum wage law for women and minors.

Recognizing that control over the processes of production lies within the jurisdiction of states, Congress resorted to its commerce powers and passed an act in 1916 forbidding the interstate or foreign shipment of any goods produced by children under fourteen or by children between fourteen and sixteen years at night work. The federal Supreme Court regarded this use of commerce powers as a subterfuge and declared the law unconstitutional as in violation of the Tenth Amendment. Congress again attempted the same objects in 1919 by levying a tax on the products of child labor. But as in the previous case, the Supreme Court looked to the real intent of the act, which was to prohibit child labor, and again held that this class of labor legislation belongs solely to the states. Whereupon an amendment to the Constitution was submitted to the states for ratification. To date scarcely a half-dozen states have approved this amendment, while a larger number have voted its rejection.

The congressional attempt to fix minimum wage rates for women and minors acting through a wage board created by an Act of 1918 applied only to the District of Columbia, but if upheld would have given solid support to and paved the way for an extension of this type of legislation, which already existed in several states. As the act came before the Supreme Court, only its application to adult women was involved. In its decision, the court refused to recognize the right of Congress to deprive adult women of freedom to accept any wage offered to them.

These unsuccessful attempts at legislation for special groups illustrate not only the difficulties in the way of class legislation, but also two of the general constitutional safeguards of personal liberty.

Social Legislation. The sixth and final class of laws within the scope of this survey concerns large numbers of families who are economically insecure and whose sole support is industrial employment. These laws are of general application and are more properly labeled social legislation rather than labor legislation although they sometimes directly affect employment. Included here are the compulsory school attendance laws, mothers' pensions, old-age pensions, credit unions, cooperative, and mutual benefit societies. In the case of old-age pensions, the number of states with existing laws is small, but nearly all states provide pensions for mothers of needy children, while statutes bearing on cooperatives and mutual societies are quite extensive.

The administration of labor law falls upon various branches of the government. Chief among them are the departments of labor and industry which have been set up under diverse names and forms in practically all states. Factory inspection service, compensation commissions, bureaus of vocational education, are but typical of the special state administrative agencies in industrial relations. The federal Department of Labor, created for the first time in 1913 as a major department of the government with representation in the cabinet, has eight bureaus devoting attention to labor statistics, immigration, naturalization, child labor, women in industry, employment, conciliation, and industrial housing. Other federal agencies, although this list is not complete, include the safety division of the Bureau of Mines, Board of Vocational Education, and special commissions on industrial relations, immigration, employment, and unemployment.

Principle of Labor Legislation Established. Thus the mere enumeration of the kind of laws through which the Government functions in the field of industrial relations presents an imposing list. We have been so accustomed in the United States to the idea of voluntarism in our industrial life that the extent of prescribed action has escaped the attention of many of us. Seventy years ago there was but a handful of labor statutes. Fifty years ago there was no defined constitutional law of industrial relations. Only since 1900 and particularly since 1910, have the rights of employers and employees become clarified, and yet only partially so. But in this period of a half or three-quarters of a century the accretions of statutes and decisions which go to make up the law of labor have been growing steadily until today, the question so often voiced in the United States: Shall we have labor legislation or voluntary action in industry? has given way to another: What kind of labor laws shall we have and how far shall voluntary action in industry be limited?

Trends of Labor Legislation. It is a fair question to ask whether this undeniable trend toward governmental responsibility in industrial relations is leading us? To attempt a conclusive answer would be foolhardy. One or two road markers do, however, seem clearly to point the direction in which we are traveling. The first of these shows a preference for that kind of governmental activity which *keeps the leadership in industrial relations in the hands of those directly involved in production processes*; that which establishes through its laws and administrative services rules of conduct which tend to preserve the liberty of individuals and minorities within the terms of the constitution. Governmental activity of this type is antipaternalistic; it democratizes the forces of production and rests the responsibility for social discovery in an

industrial order directly upon the participants. Government, guarding the interests of the people as a whole, thus assumes the roles of a referee and of a service agent. A careful examination of the governmental action in industrial relations in the United States seems to reveal these primary characteristics.

The second sign post, that which points to the increasing establishment of labor standards, might appear to be contradictory to the one just mentioned, unless the distinction is recognized between laws which regulate working conditions and those which undertake to control human relationships. The bulk of legislation in the United States is in the former area. Furthermore, the range of its application is in the lowest order of industrial conditions. Complete or even approximate standardization of working conditions as a goal is generally abhorred in the United States, but viewpoints and legislative practice are unmistakably working toward the establishment of *minimum levels below which industry is not permitted to operate*. Labor of children under fourteen years, the safeguarding of dangerous machinery, and the prohibition of women working in underground mines are examples of such minimum standards. To permit these and other practices or conditions, it is forcibly argued, would tend to undermine the stability of the vast majority of industry. Many are the differences of opinion as to what these minimum standards should be but as to their utility and desirability in numerous circumstances there is relatively little dissent. Those who argue otherwise place themselves in a strategically weak position when the time comes for determination of the level at which the minimum requirements may be fixed.

Finally, there is the indicator that *social insurance against the hazards of industrial life* is already an established institution in the United States. With state accident compensation and mothers' pensions laws already well-nigh universal, with the state old age pension movement in full swing and with agitation of state unemployment insurance reaching the point of advocacy by the governor of a premier state, a potential candidate for the presidency of the United States, there can be no mistaking the course of social insurance in this country.

CHAPTER I

ORGANIZATION AND FUNCTIONS OF MANAGEMENT

DECENTRALIZED OPERATIONS AND RESPONSIBILITIES WITH COORDINATED CONTROL

BY DONALDSON BROWN, *Vice President, General Motors Corporation*

There is probably no subject relating to industrial management more important than this. Yet, very little has been written which deals with it in a comprehensive way. There is good reason for a hesitancy to lay down general rules. The problem involves theories of psychology on which there is no lack of authoritative references, but a practical application of such theories is circumscribed by the personal equation and peculiar circumstances in individual cases.

General Motors Corporation employs approximately \$1,300,000,000 of gross assets, something like 175,000 employes, and comprises a large number of separate and distinct operating divisions. Among these separate divisions are the car divisions, owned directly and embracing Buick, Cadillac and La Salle, Chevrolet, Oakland and Pontiac, and Oldsmobile, which are recognized as leaders or else among the largest automobile producers in their respective fields. The Fisher Body group supplying automobile bodies to the car divisions is owned and operated as a division of General Motors and, in itself, is one of the largest businesses in the United States. Also there are numerous divisions manufacturing parts and accessories for automobiles, each one a highly specialized business and, in most cases, selling product in competitive markets as well as to our own car divisions.

Obviously, such a condition renders it impossible for General Motors to have a centralized organization in the sense of functional responsibilities. Each one of its divisions, from the standpoint of administrative management, has a fully self-contained organization, with a general manager responsible over all of the usual functional activities, such as engineering, purchasing, production, and sales; and including financial control. Yet, as an institution, having to account to its stockholders for constructive progress, General Motors must justify its corporate existence. There must be a sound measure of centralized control so as to assure the proper coordination of its various activities and the ability to capitalize, to the maximum degree, the great advantages derived from its combined size and importance in the industrial world.

Similarity of Fundamental Principles of Management. It goes without saying that the experience of General Motors has only a limited application to most other businesses. Obviously, its problems differ materially from those

of a less diversified business whose directing management is in immediate contact with all operations. There is a similarity of fundamental principles, however, and a brief outline of our own experience may prove of use as introductory to further study.

The fundamental principles of management which are applicable to any industrial business today need mention in order to illustrate the adaptation of those principles in our own particular circumstances.

Initiative Must Be Encouraged by the Delegation of Authority. All of us have a full appreciation of the importance of promoting initiative and enthusiastic effort down the line of organization by the delegation of authority and placement of responsibility. The difficulty in executive management is not in recognizing the advantages of placing responsibilities, but rather in distinguishing where limitations should be placed in order to gain necessary coordination.

By responsibility we mean the exercise of prerogatives, either implied or specifically assigned to the jurisdiction of an individual. Accountability would be a better word, for the individual who delegates authority does not divest himself of responsibility. The clerk has responsibilities which are assigned to him; the shop foreman has responsibilities under the jurisdiction and guidance of the shop superintendent; the general sales manager is responsible for sales, but he is expected to delegate authority to those under him and to hold each responsible in the performance of his assigned duties. Each department is responsible for the work in which it is engaged, and the exercise of this responsibility is served best by the assignment of authority and jurisdiction down the line as far as the capacity of the personnel will permit. Yet, there is the full responsibility upon the department head, and in turn the general manager, while the president is responsible over the whole. *In the sense that each individual is responsible to some one superior, culminating through a series of lines of jurisdiction in the responsibility of the president himself, central control is absolutely essential* as governing every activity in business management. This kind of control might be called administrative control; and the proper assignment of duties and responsibilities down the line of organization, as administrative management.

Men are jealous of their prerogatives. In fact, business management today has no high position for the man who lacks the courage of his convictions and who brooks interference with the duties and responsibilities which he knows to be within his rights. Promotion goes to the man who shows ability to assume responsibilities a little beyond the defined duties of his position, and the development of personnel and esprit de corps results from the delegation of authority and responsibility. But every man charged with responsibility and vested with authority must be brought to realize that his function is tributary to the accomplishment of a central motive. To whatever degree this spirit can be engendered throughout the organization, to that degree the central motive itself becomes the controlling power. There is no occasion for resentment where the functional activities of an individual are guided in the direction of an ultimate purpose, the existence of which is made known and in the conception of which the responsibility is recognized as resting elsewhere.

Permanent Welfare of the Owners Is Central Motive in Business. Since business owes its existence to its owners, it is expected to operate for their benefit. This is not inconsistent with the broader ideals of service to the public, because it is only through service to the public that profits to the owners may be assured permanently. Thus there is just one central motive in industrial management, *i.e.*, the permanent welfare of the owners of the business. This central motive, or ultimate purpose, is served through the determination of what are known as policies. Such policies as it is possible to establish in clear-cut terms must be laid down for the guidance of the administrative management. Unfortunately, it is impossible to anticipate the character of all the varied problems that present themselves in management and to embrace them by a definite expression of policy. In cases where there is no concrete expression of policy the administrative management is none the less subservient to the policy viewpoint. Where doubt exists, those responsible for policies must be consulted and decisions of policy laid down.

The Need of Coordination. In the true sense "centralized control" refers to the central motive of management. It requires that the activity of all departments be controlled so that they coordinate with the needs of the business, and with the requirements of policy. One-man control applied in the sense that one man dictates as to details of management is destructive to ultimate progress. But one-man control is essential as applied in the sense that he has a full appreciation of policy and a comprehensive knowledge of what is going on, to the end that every activity is guided in the direction of an ultimate purpose. If there is a complete coordination, with full regard to the permanent welfare of the owners of the business, then it follows that centralized control exists.

Responsibility of Board of Directors to Represent the Stockholders. Most large businesses today are in the hands of corporations owned by scattered stockholders. The corporation has a board of directors. The directors, individually and collectively, have the responsibility to represent the interests of all of the stockholders; in other words, to see that centralized control exists. Usually the board is comprised partially of men actively engaged in other directions, who cannot be in sufficiently close touch to exercise direct action in the determination of policies. This brings about the designation of a sub-committee, usually called the executive committee, comprised of board members more closely identified with the business, to whom broad authority is often delegated by the board.

But the board of directors has, and cannot evade, the sole duty of representing the stockholders. To the extent that discretionary power is left in the hands of an executive committee, it requires confidence and faith in the breadth of view and ability of that subgroup to exercise the prime function. There can be no shifting of the ultimate responsibility.

Just as in the case of the board of directors, where it is proper that broad authority be delegated to a subcommittee, so it is proper and advantageous to the stockholders that authority be conferred upon the administrative management as far as it is possible, so long as there is assurance of a proper degree of coordination, and compliance with what may be required from the standpoint of policy.

Limitations upon Committee Management. The fact that the board of directors, or we will say the executive committee acting for it, has the unescapable responsibility of centralized control does not mean that there should be committee management. If the executive committee be composed of department heads, or men actively engaged in the administrative management, it is usually advantageous because of their intimate knowledge of the problems of the business. On the other hand, this circumstance makes it difficult at times to distinguish between those questions requiring executive committee action and those questions which, in the interest of individual initiative, had better be left to administrative control. It should be recognized that the function of any individual as a member of the executive committee is quite different from his function as an executive officer. Committee action is by majority vote; executive action is by individual choice. The executive may seek the counsel and advice of any number of men on a given problem, but the decision is his. It matters not the extent to which he accepts the judgment of others, the action is his own individual responsibility. There is much truth in the saying that "what is everybody's business is nobody's business," and there can be no doubt that where committee action is applied to problems of purely administrative management it is almost always bad.

Duties and Responsibilities of Executive Committee. Having noted the necessity of centralized control and the responsibility of the executive committee in this regard, it is well to consider how its function can be exercised with no unwholesome effect upon the other phases of the management problem. The following may be laid down as the basis upon which the duties and responsibilities of the executive committee may be defined:

1. There must be a knowledge of the characteristics of the business and an understanding of the degree to which coordination exists or may be made to prevail through the cooperative activity of departments, operating under individual responsibilities and distinct lines of authority. Knowledge of the business and the use of statistical analyses suitably designed are essential to serve this first requisite.

2. Wherever practicable, it is desirable to lay down a concrete policy as establishing the fundamental basis upon which the activity of any or all departments shall be predicated. This can be done only where it is possible to express a point of policy in clear terms capable of interpretation and proper application in the varied conditions that occur and with which the administrative management must contend.

3. In the many cases where it is impossible to lay down any general rules and yet where the question of policy is no less involved, it becomes necessary to deal with problems as they arise. In this there is always the danger of encroaching upon the sphere of administrative management, and it is of great importance to analyze the characteristics of the problem so that it can be dealt with from the policy standpoint.

4. The president is the chief administrative officer and the connecting link between policy and administrative control. It has been stated that so long as complete coordination exists there is no need for the imposition of any central authority. The president must distinguish clearly between questions of policy and questions of administrative control applying to problems as they arise, and one of the most important functions of his position is to see that there is no undue interference with the prerogatives of individuals in the

organization. Where there is any room for doubt as to what may be best for the welfare of the stockholders, he must secure from the executive committee an expression of policy. In all other respects, it is the president's duty to see that coordination exists just as far as it is possible, and at the same time that those down the line have all the latitude and authority that is warranted, with a full sense of responsibility, so that there will be the greatest possible enthusiasm and exercise of initiative throughout the organization.

5. In rare cases and under unusual circumstances, where it is impossible to draw the necessary distinction as to the line of policy, it may be justifiable for the executive committee to assume the responsibility of direct action in respect to matters of administrative character. This should be avoided, if possible, and always where such a course is necessary care should be taken to point out that the question of policy is involved and that it is impossible to secure a distinct separation of policy from questions of administrative responsibility admittedly included.

General Motors Type of Organization. In the case of the General Motors, the board of directors has two subcommittees; a finance committee responsible for general financial policies, and an executive committee responsible for operating policies.

The finance committee includes men of large affairs identified with banking and with big business, apart from General Motors, while the executive committee is composed of men giving all of their time to the affairs of General Motors. In a limited sense the executive committee is subject to the finance committee in that operations are dependent upon financial policies. At the same time, financial policies must be maintained so that operations will not be deprived of any legitimate development. Cooperation, as between these two committees, is furthered by the fact of common membership on the part of several individuals.

Obviously, it is humanly and physically impossible for the executive committee of General Motors to maintain the same kind of intimate contact with the details of its business as would be practicable in the case of a very much less diversified business. Still the responsibility to stockholders is exactly the same and the proper organization of control has been forced by absolute necessity. Otherwise, the business were better split up into various units with separate ownership, even at the sacrifice of the great advantages of the existing combination, so that the stockholders of each unit respectively could elect a board of directors capable of assuming the usual responsibilities. Let us examine, first, the general way in which the separate units of the corporation are constituted.

Separate, Self-contained Divisions. Each one of these operating units, known as divisions, is entirely self-contained, with a general manager and complete jurisdiction and responsibility established.

There is never any conflict of jurisdiction, with respect to capital invested. Where any given plant produces a component entering into the finished product of just one of our divisions, it is deemed proper, unless the manufacture is of a highly specialized character, that the investment in that plant and its operation be placed under the jurisdiction of the consuming division. Generally speaking, where the product of a given plant enters into the product of two or more of our divisions, it is deemed desirable to place the investment in such plant and the full responsibility for its operation under the jurisdiction of a

separately organized division. It is thus that our numerous parts and accessory divisions derive their separate entity.

Apart from certain distinct units embraced in the Fisher Body operations, we have a group of divisions manufacturing components and accessories, such as ignition systems, bearings, and gears. All of these divisions are selling product to our car divisions and also, almost without exception, sell product outside. In addition, we have what are called our household appliance divisions which manufacture such products as electric refrigerators, radios, farm lighting and power equipment, farm water systems, illuminating gas systems, electric fans, and small motors; and another group of divisions known as the aviation operations. Each of these three groups of divisions comes under the general guidance of a vice president of General Motors.

Pricing as Applied to Interdivisional Sales. The question of pricing product from one division to another is of great importance. Unless a true competitive situation is preserved, as to prices, there is no basis upon which the performance of the divisions can be measured. No division is required absolutely to purchase product from another division. In their interrelation they are encouraged to deal just as they would with outsiders. The independent purchaser that is buying product from any of our divisions is assured that prices to it are exactly in line with prices charged our own car divisions. Where there are no substantial sales outside, such as would establish a competitive basis, the buying division determines the competitive picture; at times partial requirements are actually purchased from outside sources so as to perfect the competitive situation.

In the Fisher Body group are included separate and distinct units supplying materials such as lumber, glass, hardware, etc., for body construction. The interrelation of these units with the final body manufacture is exactly the same as that between the other divisions which I have described.

There are five automobile divisions in General Motors operating in the United States, each occupying a position in a distinct price class in the industry. There is charged to each the total investment in plants and other assets over which it has complete jurisdiction.

In addition there is a separate division handling the assembly and sale of all cars in Canada; and an export group handling the sale of all cars in other foreign countries. This latter group has charge of manufacturing and assembly, as well, where cars are manufactured or assembled abroad.

Rate of Return on Capital as a Yardstick. The general test of efficiency of management of any business is the rate of return on capital employed. Capital in industry is entitled to a varying rate of return largely dependent upon competitive conditions in the broad sense and the hazard that is involved. Needless to say good will, that intangible and illusive, but none the less valuable, asset which every business seeks to enjoy, is of great importance. Apart from this, however, profit from industry is dependent upon the character of product supplies and the degree of protection afforded by patents of specialized knowledge and skill in processes and methods of manufacture and distribution. At the same time the rate of return on capital is affected directly by the control of investment in working capital items and fixed assets in relation to the volume of business. Capital employed in the

production and sale of a product that is bought on the basis of exact specifications, in the manufacture and distribution of which no highly specialized knowledge is required, contents itself with a relatively low rate of return. The production of an article that is exclusive in design, possessing superior engineering qualities and carrying with it a peculiar appeal to fashion or the taste of the public affords to capital the opportunity of enjoying a high rate of return. The hazard which always accompanies such a condition is minimized by the exercise of skill in progressive engineering improvements, and ingenuity in anticipating the changing tastes of the buying public. In gaging the effectiveness of management the first approach always is to examine the overall result—the rate of return enjoyed on capital employed. If this be subnormal, having due regard to the character of business and the competitive situation, it is self-evident that something is wrong. The second step is to identify the cause.

Gaging Overall Effectiveness of Management. With the segregation of General Motors into separate businesses of distinct classification we are in position to compare the performance of various divisions respectively with competition in the same line. Thus we can gage the overall effectiveness of management in each case. By the use of suitable statistics and contact with the management of the various divisions, the president of the corporation and central group executives are able to detect instances of faulty control and to bring about the correction of a recognized condition by way of intelligent suggestion. The executive committee is able to deal with operating policies in respect to any division with an understanding of the characteristics of the particular business and the position of the division in its field of competition. This type of organization as applied to big business lends assistance to a high degree of centralized control, while at the same time it affords an opportunity of fixing responsibilities upon the administrative management on a clear-cut basis upon which they can be held accountable for results.

As a general proposition, I should say that in any business of considerable size and diversification, capable of being subdivided into units having the characteristics which I have described as pertaining to General Motors' divisions, such segregation is deserving of the most serious consideration. If the advantages of such a type of organization are to be enjoyed fully, it is absolutely essential that each unit be constituted so that it represent a self-contained business enterprise. The capital placed under its jurisdiction must be identified definitely with its own business and no other; and prices at which its products are sold must be based upon actual competitive values. Otherwise there is no tangible basis upon which the general effectiveness of the direct management can be gaged reliably.

Decentralized Organization as Opposed to the Centralized Type. This scheme of organization is usually referred to as the decentralized type. Opposed to this is the centralized type of organization, made up of functional departments; with an executive in charge of all manufacturing operations, another in charge of all sales, and with central purchasing and engineering departments. As to any of these functional activities it is difficult for anyone not in constant contact to judge the efficiency of performance even though he might have a specialized knowledge of the particular type of activity. With

accurate accounting practices and painstaking analyses the manufacturing cost of a given component, or the complete product of manufacture, at times may be compared with the price at which a similar thing can be purchased elsewhere. However, it is very rare that a comparison can be had with the cost of manufacture elsewhere. Also it is impossible to arrive at a conclusive comparison of sales effectiveness and efficiency. Unrecognized inefficiency in manufacture may throw an impossible task upon a very efficient sales department. On the other hand an inefficient sales department may make it impossible to capitalize a highly economical manufactured product. In any event *general managership* is needed. This is essential, not only to gain proper coordination of functional activities, but from the standpoint of having some one in sufficiently close touch with details as to be competent to size up the effectiveness and efficiency of departmental management.

In the days of small business, corporations or privately owned businesses were managed by men who had a detailed knowledge of all the functional phases of the business. Department heads, and even those below had intimate contact with the general problems of the business, and gained knowledge in the essentials of general managership. The heads of many large corporations today had their early training in the atmosphere of the small business, and know from experience the character of problems which present themselves down the line and recognize the need and method of coordinating the various activities. In the sense in which I am using the phrase, there are still many small businesses. But a large share of the country's manufacturing business today is conducted by huge corporations, brought into being by force of economic developments and the opportunity of capitalizing the enormous advantages of large-scale operation. As applied to these there is a comparatively new problem of organization. That problem is to combine the economical advantages of modern business, with as little sacrifice as possible of that intimate control and development of managerial ability that is characteristic of the well managed small business.

Most of the divisions of General Motors are enormous in themselves, but separately they do not have the complication of products of highly diversified character or type. Operating as separate self-contained businesses, the divisions afford the advantages of concentrated management inherent in the small business. It has been pointed out that, apart from these advantages, this scheme of organization facilitates the exercise of centralized control from the policy standpoint in the case of a corporation constituted as General Motors is.

Corporation Policies and Interdivisional Relations. Apart from the coordination of activities within each operating division, there are questions of corporation policy having to do with interdivisional relations. There must be no undue conflict, competitively, between the product of one division and that of another. There are certain general policies which, if good for one division, are good for all divisions. There are other questions of policy which must be determined from the standpoint of the corporation as a whole, rather than from the standpoint of any single division.

Purchases of materials must be conducted in a way so that the full advantages may be enjoyed from the combined requirements of all divisions.

Engineering developments of fundamental character must be brought to light and the adaptability determined. Manufacturing methods and policies demonstrated to be advantageous in one place must be considered for adaptation under like conditions elsewhere. Similarly as to sales methods and policies. All products sold are advertised directly by the divisions respectively. However, General Motors advertises as an institution. The institutional advertising must be coordinated with the direct product advertising; and the integrity of the corporation's position must be preserved by making sure that the advertising is according to the facts, and in line with the policies of the corporation.

Interdivisional Relations Committees Are Not Administrative. Serving in the direction of crystallizing the important corporation policies and making them effective, and to facilitate the adaptation of engineering improvements and operating methods, there are various so-called interdivisional relations committees. They have suitable representation from the most important divisions, and are as follows: general purchasing committee, general technical committee, works managers committee, general sales committee, public relations committee, service committee, etc.

These committees meet separately at certain intervals. There is at least one member of the executive committee on each of these committees. The work of the committees clears through various central office staff organizations, maintained so as to perfect the flow of information back and forth and to facilitate the orderly consideration of common problems of important policy and procedure.

The purchasing committee deals with questions of general purchasing policy, but, by reason of the nature of the situation, it directs the actual purchasing arrangements in cases where it is found advantageous to centralize the purchases of materials common to two or more divisions. Such purchases usually are effected by a central staff organization headed by an executive who is secretary of the general purchasing committee. In all other cases, however, the interdivisional relations committees have no actual authority. They are not designed to function as administrative bodies, but rather as a means of providing an opportunity for general discussion of problems of common interest. No one is bound by the expression of opinion by others in meetings of these committees; there is no transfer of responsibility. Where there is a question at issue on the score of corporation policy the president of General Motors makes the decision or refers it to the executive committee for its determination. Cases of this kind are rare.

Substituting Facts for Opinions. As a fundamental requisite in the work of coordination, it should be remembered that the bringing of men's minds together in connection with a given problem can always be greatly facilitated through a presentation of the facts. Disagreements fade away in proportion to the degree to which facts may be substituted for opinion. So far as it is practicable the discussions in these committees are predicated upon the display of facts. Questions of policy are clarified; and through the operation of these several committees a means is provided of gaining a widely diffused knowledge and understanding of corporation policies, and a sympathetic compliance with them as they may bear upon the immediate problems of divisional management.

The head of each division should be qualified in every way to hold the position of president were its business owned and operated by an independent company. He has all the latitude and authority that normally would go with such a position, being limited only in the direction of policies such as properly would be dealt with by the board of directors or executive committee. In the actual situation such questions of policy are dealt with by the president of General Motors and group executives, facilitated through the operation of the various interdivisional relations committees, reference being had to the executive committee of the corporation when occasion requires.

ORGANIZATION AND OPERATING PRINCIPLES

BY EDGAR W. SMITH, *Assistant to President, General Motors Export Company*

Very definite principles of organization exist; they are common to all forms of activity which human beings collectively may undertake, whether political, social, military, religious or industrial in their nature, and they divide themselves into three major classifications: the scalar principle, the coordinative principle and the functional principle.

What we are concerned with is that a structure of organization arises out of a proper interpretation and application of these principles, and that this organization structure is put into our hands to utilize in an operating sense for the attainment of our established objectives. This paper aims to provide only a knowledge of what we have done in the General Motors Export Company in the way of creating an organization structure, and what we have attempted to do in the way of providing a set of operating principles for its effective and profitable use.

Use of Line-and-staff Principle of Operation. The General Motors Export Company is the division of the General Motors Corporation charged with the responsibility for distributing the corporation's products in all territories outside of the United States and Canada. It is, in fact, the consolidation of what would otherwise be the export departments of all of the corporation's car and truck manufacturing units, including the Chevrolet Motor Company, the Buick Motor Company, the Olds Motor Works, the Oakland Motor Car Company, the Cadillac Motor Car Company and the Yellow Truck and Coach Manufacturing Company. As late as 1926 the Export Company was composed of 13 different operating units; the total number of employees on the pay roll was 2,567; and sales volume was running at the rate of \$85,000,000 a year. In three years the company expanded to include a total of 22 self-contained, self-administered companies, operating nineteen assembly plants, five warehouses and three distributing organizations in 110 overseas markets; the personnel employed increased to over 19,000, and the sales volume in 1929 attained a figure of close to \$300,000,000. The program of expansion which resulted in these changes has been carried on, and is being carried on, through the medium of an organization which functions in strict accordance with the line-and-staff principle of operation. Adoption of this line-and-staff principle became inevitable with recognition of the potential size, diversity

and extent of the Export Company's business. It is peculiarly suited to the needs of such a business, and we believe sincerely that, without the strength and flexibility it has provided, our rapid growth in this short period could not have been attained.

This line-and-staff principle is not a principle of organization, but strictly a principle of operation: it is simply one of the ways—and the most effective way, I believe—in which the organization principles of delegation, coordination and division of duties can be molded to practical use in the attainment of the objectives which are being sought.

Planning a Line Attribute. The terms "line" and "staff" themselves have, very obviously, been borrowed directly from military parlance. A line officer performs actual operations, in the theatre of war most frequently, but also in the seclusion of a distant building at headquarters; and the operations he performs include both thinking and doing. The captain in an infantry regiment in France during the war was patently a line officer; so also was his regimental commander and his army commander and the commander-in-chief of the A. E. F. But—and this is a point not widely recognized—so also in fact was Gen. Peyton C. March, chief of staff of the United States Army, who sat at headquarters back in Washington. All of these officers thought and acted. They acted in the sense that they did things and exercised direct authority, but it in no wise affected their status as line officers that they should also have been obliged to think. Probably the chief element of confusion to an understanding of line and staff operations is that planning, as expressive of forward thinking, should somehow be considered exclusively as a staff attribute. A staff officer, as a matter of fact, does assist his line superior in the latter's thinking and planning. In the army, the staff officers attached to the chief of staff aid in the development of strategy and the provision of materials both of which enable the line officers—including factually the chief of staff—to carry on.

All Officers Both Line and Staff. The use of a staff is not, of course, confined to any single officer. An army commander has a staff, a corps commander has a staff, and a division commander likewise; and in the smaller units, down to the company, there are staff functions to be performed. In our organization, the general manager's staff exists in the persons of the functional department managers; these department managers themselves have certain assistants who act on frequent occasion in a staff capacity; our regional directors out in the field have their staffs, and, in the case of our managing director at each individual plant, his line lieutenants function in a staff capacity whenever they act with him as advisers and consultants. It is to be noted in this connection that no man in the organization—with the exception of the president—is either pure line or pure staff in the day-to-day conduct of his work, for staff officers execute very definite line functions in the administration of their own departments, and so typical a line officer as the general manager discharges staff responsibilities in his consulting and advisory contacts with the president. The president himself is pure line.

Possibly the simplest way of expressing the difference between line and staff attributes is to state that if the administrative head of an organisation has sufficient time and sufficient ability to study in detail and be thoroughly

familiar with all phases of the work for which he is responsible, he would not need a staff. Therefore, a staff organization can be looked upon first of all as a group of men who, at the direction of the administrative head, study and analyze problems and develop plans to the end that the administrative head may have before him the necessary facts and opinions upon which to base judgment and take action. A staff is something to lean on. This is its original meaning, from which we have arrived at the derivative sense of the term as we employ it.

The Operating Obligations. Before we attempt to apply the line and staff concept of operation in detail to our organization, it is desirable that we look first to what we may call the "operating obligations" of any industrial organization, including, of course, our own. These operating obligations are inherent in all management: existing with us originally in the president, they are delegated by him for actual pursuit and accomplishment to the general manager. In an organization of the scope and complexity of the General Motors Export Company it is necessary for the general manager in turn to delegate responsibility and authority in generous measure to his own subordinates in order to assure the attainment of his ends. It is important in this connection to note that these operating obligations again have no inherent identity with the line and staff principle of operation as such: *The line-and-staff principle of operation is simply the inevitable means that the general manager takes, in his obvious inability to do so personally, to secure the satisfactory discharge of his operating obligations.*

The operating obligations of the management are divisible very naturally under three distinct heads:

1. Planning.
2. Administration.
3. Results control.

The line-and-staff principle of operation permits the general manager primarily to delegate a large measure of the responsibility and authority for administration to his line officers in the field; it permits him, also primarily, to delegate a large measure of the responsibility for planning and results control to the staff officers by his side in New York. The authority and responsibility projected out to the line officers in the field is for all functions of operation in a restricted territory; the responsibility delegated to the staff officers in New York is for a single function of operation in all territories.

The Work of Administration. For purposes of logical development, let us discuss first the obligation of administration.

Our day-to-day business must go on. Cars must be sold and serviced; men must be hired and trained; materials must be flowed into the plants and along the assembly line and out to the distributors and dealers; the thousand and one things that happen daily and hourly must be done. No one man can do them all; no one man can even directly supervise their doing. Limitations of time, distance and human capacity determine these elemental facts. Twenty-eight individual operating units, such as those comprising the Export Company, would, even if they were located within the boundaries of a single state, be unwieldy of direct administration by a single man. The diffusion

of interest and attention among so great a number of points of operation would obviously be too considerable, and the problems involved too complex, to permit of satisfactory handling in this manner. It would be natural in the circumstances to combine the individual units into wieldy, less numerous sub-groups, and to put at the head of each sub-group a man to whom the general manager assigned the responsibility and delegated the authority necessary for its direct and competent administration. The operating units of the General Motors Export Company are not located in a single state; they are scattered over the face of the globe. This fact of their remoteness, from New York and from each other, lends additional emphasis to the necessities cited. It is for these reasons, then, and because it is desired to simplify the organization structure rather than to complicate it, that the office of regional director has been created. A regional director is placed in charge of each of the major territorial divisions throughout the world; one in Europe, one in South America, one in the Far East, and one in Australasia.

We are, therefore, brought to the first step in the definition of our organization chart: The general manager has delegated to the regional director, as line authority and responsibility, a large measure of the company's operating obligation having to do with administration, and the regional director accepts this authority and responsibility, for his particular block of territory, in all of its functional elements of management, sales, finance, manufacturing, and supply (see Fig. 1).

FIG. 1.

Planning and Results Control. Let us turn now to the other operating obligations of planning and results control.

By the same reasoning that goes to establish the impossibility of direct administration of all territories in the world from a single source, it is obvious that the planning, coordination and checking of results under their various primarily specialized aspects of sales, finance, manufacturing and supply, are equally a practical impossibility. The general manager finds it expedient and necessary in these circumstances to allocate the responsibility for doing the greater part of this work to a number of men, each of whom is charged with assisting and advising him in the particular field for which he has been chosen. The so-called "functions" of sales, finance, manufacturing, and supply are simply the logical and convenient avenues of specialization which have arbitrarily been determined upon; the word function itself has no particular operating significance beyond its meaning of specialized activity; management itself is a function; publicity, service, and inventory control are functions subordinated to certain others for ease of classification and government. Thus in discharging his operating obligations of planning, in so far as it applies to the elements of the business that have to do most closely with the sales activity, the general manager looks largely to the general sales manager for staff aid and counsel; he looks similarly to the general manufacturing manager for planning as it has to do with the functions of manufacturing; and

he looks to each of those officers, respectively, for staff aid and counsel in relevant matters pertaining to his own operating obligation of results control.

The next step in the organization chart, therefore, is to show the introduction of the four major functional staff heads in New York, as well as of one or more other staff officers, either functional or general, on all of whom the general manager leans for every necessary support (see Fig. 2).

We see, then, that a line officer—typically the general manager—is responsible for the three major operating obligations of planning, administration, and results control. Planning and results control he delegates largely on a functional basis, to his functional staff, the heads of the four departments of sales, finance, manufacturing, and supply; this delegation is one involving responsibility alone. The obligation of administration he delegates in a line sense, including both responsibility and authority, to his line officers in the field, the regional directors. The regional director is actually the representative of the home office in the field; he is, in one sense, a territorial general manager, who happens to be located out on the ground instead of being located somewhere down the corridor in the New York office. The virtue of the regional director's position rests, of course, in its consonance with our company's accepted policy of projecting authority out closer to the sphere of actual line operation; the test of the nature of his work is simply that he should do, in his particular field, what the general manager would do if, ubiquitously, he could be in each region.

This brings us to the next step in the construction of our organization plan.

The regional director, himself a line executive, inherits for his particular territory the same three major operating obligations of planning, administration, and results control, in all of their functional phases including management, sales, finance, manufacturing, and supply. He is, of course, responsible for the satisfactory discharge of his obligations in these respects directly to the general manager, and he receives his authority directly from the general manager; that is to say, there is no line of direct authority running down to him from any of the staff executives in New York, nor of responsibility running up to them from him.

In the discharge of his own operating obligations, the regional director, who has been placed in charge of a subgroup of individual operating units, looks to them in exactly the same way that the general manager has looked to him. There is the identical necessity, in only lesser degree, for delegation of authority and responsibility to the next stratum of organization beneath him; there is the identical requirement for the creation of more intimate administrative media and for the creation of more highly specialized planning and results control media; and there is the same opportunity and logic for utilization of the line-and-staff operating principle in the accomplishment of these ends.

In the same manner that the general manager delegated it to him, therefore, the regional director proceeds now to delegate to each of his individual managing directors the responsibility and authority for the administration of each of the particular operating units going to compose his region, under all of the major functional aspects of management, sales, finance, manufacturing, and supply. We show at this juncture the addition to the organization chart resulting from this development (See Fig. 3).

By the same cause that moved the general manager to proceed similarly, the regional director now delegates to staff officers he has appointed the responsibility of assisting him adequately in the discharge of his territorial operating obligations of planning and results control: to a regional sales

FIG. 2.

FIG. 3.

manager for the sales phases of this work, and to regional finance, production, and supply managers each for these respective functions. He may also, as did the general manager, have one or more general staff officers whose work is not functionalized; the assistant to the regional director is typically such an officer.

Our organization chart has now assumed these proportions (see Fig. 4).

The third stratum of the organization now finds the managing director, a line executive, possessed for his particular plant of the same three major operating obligations of planning, administration, and results control. The manner in which he carries out the discharge of these obligations is generally similar to that in which the general manager and the regional director carried out theirs before him: authority and responsibility are again necessarily delegated, this time to the officers in his own organization who are closer to the field and to the various functional responsibilities than he is himself. In one important respect, however, a difference exists: inasmuch as we have at last reached the ultimate field of operation—the very theatre of war—the

FIG. 4.

managing director finds it both feasible and desirable to delegate to his functional department heads, not only the responsibility for planning and results control, but also the authority for the exercise of this planning and results control and the authority as well for the administration of each respective function. The functional department heads at the plants, therefore, in contradistinction to the functional department heads in the region and in New York, are line officers. It is true that they discharge staff duties when they consult and advise with the managing director, but they are line officers essentially; the manager director's staff proper is composed of one or more assistants to the manager director.

The last step in the skeleton structure of our organization shows, therefore, the following set-up existing (see Fig. 5).

It would be possible to carry the organization chart down further still, and to show how the sales manager at a plant delegates his authority to zone

managers and fieldmen, and how in turn he fortifies himself with a staff of commercial vehicle experts, transportation engineers, and individual car-line specialists. It should suffice, however, to leave the organization structure at this point, below which, in any event, as will be seen, the contact from New York does not flow.

Before proceeding to a discussion of the lines of contact existing within this organization structure (other than the lines of direct authority made evident on the face of the chart), it will be interesting to look for a moment at a few of the essential factors in the broad descriptions that have been given to the line-and-staff offices portrayed. It was said in an earlier paragraph that no

FIG. 5.

officer, other than the president, is either pure line or pure staff in the day-to-day conduct of his job. This is entirely true, but the fact in no way lessens the desirability of identifying an executive in the organization polity as either essentially line or essentially staff; a correct understanding of the relationships existing requires, in fact, that this be done. The general supply manager, for example, is essentially a staff officer in the place he holds in the polity of the organization as a whole, and this is true despite the fact that he performs, by himself or through his assistants, such obvious line duties as the movement of freight to seaboard: in such an instance he is, of course, acting in a line capacity with respect to his own subordinates, as all officers must.

The point is, of course, that a staff officer does issue line orders to his own departmental subordinates, but that he cannot issue orders, as a line officer

can, to the body of organization that lies in the various strata beneath him on the organization chart. In other words, a line officer exercises authority over all of the body of organization lying beneath him on the chart, whereas the influence exerted by a staff officer outside of his immediate department is, so far as it is authoritative, an authority of ideas. The staff officers are, in their functional capacities, responsible advisers to their respective line superiors, and advisers also to the corresponding staff officers in the subordinate organization strata, but any direct line instructions they may wish to see promulgated may be promulgated only back through their line of contact with their superiors and down thence to the line officers in the next subordinate stratum. It will be noted further along, however, that direct contact regularly exists between staff officers as, for example, between the general sales manager in New York and the regional sales manager in the field. This contact is not a line contact, nor an authority contact: it is a contact of an informational and advisory nature.

Again, before proceeding in detail with a definition of internal organization contacts, it is desirable to look a little more closely at the three major operating obligations of planning, administration, and results control, in order that a better understanding may exist of the nature of the contacts involved when we come to discuss them.

The element of administration, since it is purely of a line nature in its discharge, is deemed to be fairly obvious; it is the thing the plants, as the ultimate units, are doing day after day in the actual pursuit of their objectives. It may be worthwhile, however, to mention specifically one element of administration going somewhat beyond the obvious up-and-down exercise of authority: this is the element of coordination, which requires the establishment of adequate liaisons, interdepartmentally and intradepartmentally, for the smooth and efficient functioning of the business in all of its phases.

The elements of planning and results control, since responsibility for their attainment is delegated largely by the line officers to functional staffs, may well be gone into a little more fully.

Planning. This obligation, a line responsibility delegated largely to functional staff officers for pursuit, embraces the following major elements, which have the specific purpose of directly facilitating operations and improving results:

Formulating general strategy and originating specific programs.

Engineering new projects.

Developing or adapting new technical or manufacturing processes and assisting in their introduction and proper use.

Developing, elaborating, interpreting, and assisting in the digestion of suitable methods and practices; assuring that superseded or obsolete methods and practices are discontinued.

Analyzing existing forms of working organization and performance and recommending changes to improve results or to meet changed conditions.

Developing methods of personnel selection, training and appraisal, and assisting in their application; and, where desirable, carrying on special training work or the supply of special personnel.

Reporting to the immediate line superior on the suitability of specific plans to the purposes of the general plans that have been developed.

Maintaining adequate liaison with corresponding functional officers in other strata of the organization; keeping generally informed as to activities and developments in all strata of the organization.

Recognizing an advantageous policy or practice developed at one point, and making knowledge of it available at all other interested points.

Assuring finally that plans are properly interpreted and understood at the destinations for which they are intended.

Results Control. The delegated staff responsibilities under this line obligation have to do with the following up and scrutinizing of results being obtained, in order (1) to bring to light weak spots in organization, methods or personnel, so that necessary remedial action may be taken, and (2) to provide a basis for setting objectives and forecasting probable performance. More specifically, these responsibilities include:

Developing and recommending such procedures as are necessary properly to program or budget the work, and compiling, summarizing and analyzing information with respect to plans or budgets.

Reviewing, summarizing and analyzing appropriate reports, and bringing to the attention of the line superiors the pertinent facts they reveal.

Making such inspections and checking such data as are necessary to secure an adequate picture of the operating conditions and results; making these findings readily available, giving them proper interpretation, and recommending remedial measures.

Informational and Advisory Contact between Home Office and Region. With these major points indicated, in however brief detail, it is appropriate now that we pursue the examination of our organization chart further to see how, as the next essential, the structure we have portrayed is bound together with lines of contact and communication; how, in other words, the conduct of business and of operational procedure is designed to flow from the line and staff organization in New York through the line and staff organization in the region and to the line and staff organization in the ultimate field, and in the opposite direction as well.

According to the organization structure portrayed in the preceding chart, the only contact for the administration of the business and for the transmission of orders and instructions between the home office and the region is the one between the general manager and the regional director. Since everything in the nature of policies and plans is designed to clear through the general manager, it is obvious that the volume of material passing over his desk is likely soon to become so voluminous that he cannot cope with it. Requests from the field for further information on policies; suggestions of a relevant nature, and more or less detailed discussions of proposed moves, will all inevitably flow in from the regional director. All of the correspondence and contact involved is important, but certain of it is sure to be of relatively greater importance. The general manager is forced to the conclusion that distinction must be made between those things which he should or can afford to handle directly with the regional director, and those other things—largely distinguished as being of an advisory and informational nature, for the distinction is only partly on the score of relative importance—which can,

because of their relevance to a particular function as apart from their overall management significance, be most expeditiously handled directly between the department head in New York and the regional department head in the field.

The same situation in all of its elements applies as between the regional organization and the plant organization; and in certain instances also, mainly in those of a strictly routine nature, as between the New York department head and the corresponding department head at the plant itself.

Thus there arises on the organization chart a line of "informational and advisory contact" which runs between each department head, division head

FIG. 6.

and section head and the corresponding department head, division head and section head in the other organization strata. For purposes of simplicity and ready identification, these lines of informational and advisory contact are shown in the chart only as they exist for the department heads themselves; they exist also, however, as between the head of the parts section in New York, for example, and the head of the parts section in the plant, or as between the regional advertising manager and the advertising manager in the plant (see Fig. 6).

These lines of informational and advisory contact have very naturally been set up in our organization structure to facilitate the flow of work and to

confine direct management contact to those matters which warrant management attention. There is created within the structure, in effect, a conception of three horizontal strata or physical groups—the home office, the regions, and the plants—held in relationship and alignment by a vertical tie of line responsibility and authority, and reinforced by four main vertical ties corresponding to the four major functions; or in other words what might be termed a line “organization of execution” and a staff “organization of ideas.”

Delegated Authority. There is one other line of contact to be indicated on our organization chart before it can be considered complete. This is the

FIG. 7.

line of delegated authority—"specially delegated authority," it might more properly be called, since direct line authority itself exists by delegation—running from the New York staff heads to the regional director, and from the regional staff heads to the managing director. This delegated authority, to exist, requires specific designation, and it is exercised exceptionally and on special occasions, rather than as a matter of course. It must be recognized as a legitimate contact, however, and our completed organization chart, therefore, includes it (see Fig. 7).

Organization Structure Must Be Intelligently Used. An effort has been made in these recent paragraphs to define rather specifically the three types of contacts and relations which prevail between the various strata of our organi-

zation. They embrace, first, lines of direct authority; second, lines of informational and advisory contact; and, third, lines of specially delegated authority. The successful day-to-day operation of our business demands a great deal of common sense and good business judgment in the exercise of these contacts. A functional staff head needs clearly to appreciate the necessity for proper coordination, and he should, as a matter of working habit, handle through his superior and over his superior's signature those things which are of management aspect; he should clearly differentiate between matters of an advisory, informational, or routine nature which can be taken up directly by him with his corresponding functional head, and things of a management aspect which should go through his line superior. The staff head in the field should likewise appreciate his responsibility to deal up through his superior, rather than direct, on matters involving policy or having management significance. He should further appreciate his responsibility to keep his line superior currently informed as to activities he is undertaking or decisions which have been reached without the management's knowledge. The lines of informational and advisory contact have been provided, after all, to speed the tempo of our business and to make our organization more flexible and more effective in its functioning; it is important, therefore, that judgment and common sense be exercised in the practice of these contacts, for vitiation of their spirit and intent through carelessness or lack of discipline can have as its only consequence the exactly opposite result of conflict, inefficiency and confusion.

This paper has confined itself until now primarily to an exposition of the structure of the General Motors Export organization and the establishment of contacts to enable its proper functioning. The vehicle we have built for ourselves, however, can take on reality and become a vital and productive thing only through its intelligent and effective capitalization and use. The concepts involved must be sympathetically regarded and practised; each individual must understand and accept his own responsibilities and authority and the responsibilities and authority of those with whom he comes in contact; the implications of subordination and discipline which are involved must be rigidly adhered to.

In the delegation of authority contemplated by our line-and-staff structure, the very scope of our activities makes it imperative that the line officer who has fallen heir to the administrative responsibility be allowed to conduct his operations actively and in an unhampered manner. Thus a managing director, in the day-to-day conduct of his business, should be able to anticipate that his work will be interfered with only in the event of some drastic shortcoming in organization, methods or personnel making itself apparent in the results displayed. If such shortcomings become manifest, corrective action is, of course, necessary and to be expected; but with the business running in a generally satisfactory manner, it is the paradoxical fact that the regional director owes a responsibility to the managing director—and each line superior similarly to his subordinates—to respect the action the managing director is taking, to give him the utmost of his support in what he does, and to accord him the maximum of credit for it. No line superior who has a proper sense of his position can afford to interfere unduly with the work of

his subordinates; the fact that he has made them his subordinates and delegated a large measure of authority to them implies a faith and trust in them that carry very definite attributes of responsibility.

Relationship between Line and Staff. The other element of responsibility which does not show on the organization chart, but which is no less existent from its moral nature, is the responsibility that a line executive owes to his own staff executives and to the staff executives in the stratum of organization immediately above him. If the expression descriptive of a staff officer's authority—an "authority of ideas"—means anything at all, it means that the staff executives' plans and recommendations are entitled to the respect and consideration of the line executive. A very definite burden is, therefore, put upon the line executive who sees fit to disregard or to reject the counsel and help of his staff associates. Since the staff executives attached to the general manager are, in a sense, the vicars of the general manager, it is quite logical for the general manager to tell the regional director that respect for the recommendations of the New York staff executives is their due, and to let it be known that the support given to the regional director will be contingent in large measure upon the spirit with which the regional director himself cooperates with the general manager's staff.

It may assist in an appreciation of this point of view to set forth four cardinal principles which enter into a proper understanding of the relationship between line and staff, and the place, respectively, of line and staff in our organization structure. These principles may be briefly summarized as follows:

1. Line and staff are jointly responsible for performance.
2. A line officer discharges his responsibility by taking direct action; a staff officer discharges his responsibility by furnishing information and advice which he makes available to the line officer unselfishly and without thought of personal credit for the results accomplished.
3. Although staff executives are charged with responsibilities that have to do with internal administrative phases of the work in their own departments, this does not give them direct authority over the line forces in subordinate organization strata, nor does it relieve their line superiors of the basic responsibility for the results of their work.
4. The line recognizes the purpose and value of the staff and makes full use of its advice and assistance. In order that the line may properly do so, the staff must create for itself an authority of ideas, and must, by competence and tact, obtain and justify the line's confidence.

The opportunity to use this organization medium which has been made available to us depends, first upon an understanding of its principles; second upon possession of the wherewithal—satisfactory product, ample capital, adequate physical facilities and trained personnel—to move forward aggressively under these principles; and third upon the will and capacity to adhere to them, to subscribe wholeheartedly to their letter and spirit, and to do a good job well.

Summary. I have attempted to cover the reasoning underlying the creation of such an organization as ours, the structure and contacts of the organization itself, and the broad elements necessary for effective operation under its essential line-and-staff principles. To summarize as briefly as possible,

this organization plan involves a structure and a series of contacts conceived in accordance with line-and-staff principles of operation, under which the management is responsible for the three operating obligations of planning, administration, and results control; under which a large measure of responsibility and authority for administration in all of its functional aspects is delegated territorially to the line executives in the subordinate strata of the organization, and under which a large measure of responsibility for planning and results control is delegated functionally for all territories to immediate staff subordinates. Reference has been made consistently throughout this paper to the delegation of administration authority and responsibility to line officers in subordinate organization strata, and to the delegation of planning and results control responsibility to immediate staff assistants. This has been done, for purposes of simplicity, in a way generally that might indicate, except for the hints otherwise given, that they are the only forms of delegation existing. They are, in fact, the most important and distinguishing forms of delegation, but the picture is actually somewhat more complicated. The line executive in reality delegates to his line subordinate authority and responsibility not only for administration, but also for planning and results control, both as they relate to his particular territory, as witness the statement: "The regional director, himself a line executive, inherits for his particular territory the same three major operating obligations of planning, administration, and results control." Furthermore, the line executive delegates to his staff subordinates not only the responsibility for planning and results control, but the responsibility and authority as well for administration of the affairs of their respective departments.

This condition of parallel and coincident delegation has been referred to in the text only where it was believed that the reference would clarify and not confuse the major identifying issues involved. These major issues remain, as consistently cited throughout the paper, the delegation of administration responsibility and authority to line executives, and the delegation of planning and results control responsibilities to staff executives. The line-and-staff principle itself, to use the words previously employed, is simply the inevitable means the general manager takes, in his obvious inability to do so personally, to secure the satisfactory discharge of all three of his operating obligations of planning, administration, and results control. It is the means by which, as human beings, we are led naturally to pool our resources to get a job done quickly and well; in view of the size, diversity, and extent of our business, it is the only means we have found that will work successfully.

MANAGEMENT FROM A DISTANCE¹

BY DR. EDMOND LANDAUER, *Managing Director of Several Continental Textile Companies, Secretary International Committee on International Management Congresses*

Some months ago I sent a telegram from Brussels where I lived to the technical director of a Roumanian weaving mill which I manage. This

¹ Presented at the International Management Congress held at Paris, June, 1929
Translated by Edith King Donald.

telegram said: "Examine friction gear coupling Diesel motor cracked bolt." Some days later I received a letter from my director advising me that upon receipt of my telegram the friction of the coupling gears of the Diesel engine had been inspected and that one of the bolts tightening the jaws had indeed been found cracked. In ending the letter my director begged me to explain how I had been able, 1,615 miles away, to detect a small mishap which he, on the premises, had not been able to locate. I strongly suspect my personnel of having seen a little sorcery in this incident. The fact is, the explanation is simple and my telegram was the result of logical reasoning.

All the weaving mills over which I have control make statements each week of the output of each quality, working on a set theoretical ideal output equal to 100 per cent. From the total of these particular outputs is established, each week, the average of the mill. All these outputs are recorded on diagrams which are submitted to me and permit me at a glance to follow the changes in output through the course of a year. Every important variation immediately brings from me an inquiry as to the cause. Likewise the superintendents who notice them accompany each change with an explanation.

In the case I am considering the curve of output which had been kept up to between 76 and $76\frac{1}{2}$ per cent had abruptly fallen to about 71 per cent as the chart indicated. During the twenty-ninth week, which showed the decline, the superintendent had notified me that the sudden slump in output was due to the employment of a number of unskilled apprentices who had caused the lowering of the general output figure. He promised me that this decline would only be temporary and that after a few weeks of practice the new workers would come up to the general level of production.

The explanation seemed logical enough and might have satisfied me, but experience had taught me never to accept without verifying the explanations which are given to the managing director to justify a drop in production or a flaw in quality. It is only human for the interested person to try to shield his responsibility. It is unusual to receive a deliberately false explanation, but it is quite ordinary when not finding the exact cause to admit a non-verified hypothesis which removes the responsibility from the boss.

Verifying the Hypothesis. In this incident I set about verifying the hypothesis, "apprentices." As I have said above, each mill records not only the average output but the output for each quality. I then examined the charts showing the output of each quality and discovered that all the charts showed a drop. The mill in question has a standard production of four qualities, two easy to weave and two much more complicated. The beginners are never put at weaving the difficult qualities at first, but advance to them only after at least a year of work at the mill. The hypothesis, apprentices, then was false, since production had also fallen off for the difficult qualities on which beginners never work.

In establishing the importance of the decrease, in per cent of the previous average output, for each quality and for the whole mill, I came across the interesting fact that the drop was the same for all qualities and equal to about 7.3 per cent. The decline being mathematically the same for all the looms of the mill the inevitable conclusion was that the cause of this decline was *a general cause working in the same way on all the looms.*

Furthermore there is only one cause of a general character which could influence the production of all the looms in a strictly identical proportion: the speed of the transmission. Hence the logical conclusion: the drop in output proved that the transmission had abruptly fallen 7.3 per cent.

Now what could be the cause of this lessening of speed? There are only two possible hypotheses: (1) The motor turns more slowly; (2) the friction of the coupling gear placed between the motor and the general transmission slides. The first supposition could be set aside immediately, since the machinist of the works sends me each evening the chart of the progress of each of the motor cylinders with a tachymetric statement of the speed. But this was normal. There remained then the second hypothesis: an abnormal sliding of the coupling gear friction. This coupling operates through jaws like wooden points on the periphery of a steel pulley. These jaws are four in number and are closed by the action of two bolts. The breaking of a bolt renders the tightening imperfect and the coupling gear slips. The breaking of the two bolts would cause the stopping of the whole plant.

The logical hypothesis scientifically deduced from the study of the facts was that one of the bolts was cracked; hence my telegram. This fact would not in itself be of importance if it did not reflect several principles of the method which allows a manufacturer to manage efficiently, even at a distance, several enterprises or groups of enterprises.

Need to Control at a Distance. The tendency of modern industry is towards great international and national consolidations, which permit a more rational division of manufacture, a lowering of the net cost and the best distribution of products; hence the numerous fusions and mergings of interests to which some give (wrongly) the name of "rationalization." But the creation of these great extended enterprises has caused a problem which is new and peculiar to our age: the method which allows the chief executive of large organizations to perform in an effective manner the general direction or administrative role in the sense of Fayol.

How can a human intellect foresee, organize, govern, coordinate, and control at a distance, from a central point, a number of plants, too far removed from each other for the permanent presence of the managing director to be possible and employing thousands of workmen and engineers each of whom can become a waste or a loss to the enterprise? It is a known fact that many of the enterprises which progress well when they are small are in danger when expanded. This arises from the fact that in a small business the direct supervision of the boss can take the place, to a certain degree, of method; whilst in the large undertaking the task goes beyond the personal possibilities of the most active men. It is in this method that scientific management applied to general direction becomes indispensable.

It would perhaps be tedious to set forth in detail the formulas by which such an organization is managed from a distance. I shall therefore only state the principles, the details of accomplishment without going from one enterprise to another.

The Exception Principle. The first essential in order to direct a group of enterprises from a distance is to be warned automatically of all that happens that is irregular. This is what Taylor called "the exception principal," a sort

of "filtering" organization which arranges the time and energy of the head in allowing to come to him only such things as require his attention.

This requires two things: reports and standards. By the reports one is informed of what happens. By means of the standards the figures of the reports can be easily compared with other figures considered as standard.

Reports. These cover various periods and assume the most diverse forms. The chart which the mechanic of the machine shop dispatches to me every evening at six o'clock is one. The detailed schedule which the plant's chief accountant sends me every four weeks is another. In a general way they are all planned to be short and clear, calling for as little writing as possible. Useless official formality, "red tape" as the Americans say, is one of the dangers into which one easily falls in entrusting the elaboration of the contents of reports to persons who are not thoroughly experienced and who do not know how to segregate that which is essential for the control of operations. The accountants, many of whom view industrial statistics as an end rather than as a means, oftentimes multiply and add to the reports unnecessarily, which entails additional work, increased expense and an enmity on the part of the technical personnel, who always have a more or less avowed scorn for "papers."

When an organization of some consequence has operated for a certain time it recognizes undeniably the spontaneous springing up of various records and red tape, which if not watched, ends in slowing up the administrative machine. I watch all the reports closely which come direct to me. As to the others which ought normally to pause *en route*, at least once a year I personally make a "visit to the newly born" and simplify or cast ruthlessly out all those, the necessity of which has not been clearly demonstrated to me.

This is not always easy, for there are superintendents, who, to prove their importance, exact voluminous and involved records which they hardly ever consult. I have many times done away with this condition without having to resort to a veto, always unpleasant to give and to receive, by using a little trick. I have knowingly introduced flagrant errors into the reports which I thought too weighty. Nine times out of ten these errors passed unnoticed. It was then easy to insist on the suppression of statistics which the one concerned had not verified.

According to the nature of the records which they reflect, the reports are dailies, weeklies or cover four weeks. Four weeks represent the greatest unit of time and correspond to the "social year." A complete balance sheet with assets and profit and loss statement is set up for every four weeks for all the plants. There are therefore thirteen "commercial periods" in the legal year. This division of the year into thirteen periods of four weeks has the great advantage of letting everything in the situation be seen perfectly clearly. It prevents disagreeable surprises and facilitates forecasting; also it is more difficult to commit an irremediable error in four weeks than in a year. As these schedules and concentrated reports of production and sales are sent to all administrators, they are always well informed about the course of affairs. The meetings of the council can be less frequent, shorter, and more effective.

The plants send out:

1. Daily:

A report of the orders received.

A report of the shipments, which is done simply by sending me a copy of the invoices.

A detailed explanation of all the complaints received.

A technical report, as to quality of product of each machine in the plant. This report is made very quickly at the end of the day on diagram reports by means of conventional symbols.

Charts of the progress of the motors, of the boilers, of the temperature and degree of humidity of the rooms. These charts are made by an automatic registering apparatus and do not call for any work on the part of the personnel.

2. Each week:

A report of the orders late in delivery with an indication of the cause of the delay.

A report of the stock of raw material and that necessary for the orders on the books.

A report of the financial operations.

A report of the production by department and machine, with the percentage of waste.

A report of the orders by kind of work, with general averages.

An analytical report of working expense in proportion to production.

An analytical report of the salaries earned.

A report of the personnel turnover.

3. Every four weeks:

A complete schedule with an account of profits and losses.

A detailed analysis of the net cost for the period.

A detailed analysis of bills to be collected with an indication of contingent delays.

A detailed analysis of general expenses.

A comparative table of the balance between production and sales.

The first group of reports informs me of the daily progress of the work and on the turn of affairs. The second keeps me informed of the way in which the mill operates. The third gives me the results.

The plants and the salesmen likewise send me each day a copy of all correspondence exchanged between them or with outsiders. These copies, which are made on thin paper at the same time as the original do not call for any additional work and automatically keep me informed of what goes on in each mill. Not much time is necessary to read these copies, for with a little practice one distinguishes easily at first glance the purely routine correspondence. The others allow me to follow and observe closely and from a distance all that passes between the plants and the salesmen, between the salesmen and the clients and between the clients and the works. Informed of everything I intervene only in important cases or when an error is about to be committed. In this case my intervention is immediate.

The mills which operate the best are those to which I write the least. This system of control saves my time and screens me from seeming to drive.

To leave a superintendent, a director, or an employee to do his work without control is to see one day, by expensive losses, that he has not done his whole task. To complain, to blame, and finally to dismiss is the usual method of management, especially dangerous when applied from a distance. I have solved the problem in obliging each one to inform me at frequent intervals and

in a precise manner, what he is doing. In this way I teach each one to superintend himself. I make no remark to the employee who reported to me: "I was intoxicated and slept all day." For a man with any dignity to have to report the thing to his employer will be ample guard against a recurrence. My principle is the opposite: "Do what you will but tell me about it and see yourself that that which you have done corresponds with the model task which I have set you."

Standards. Obliging each worker, each foreman, each superintendent to report at regular intervals has above all a psychological effect of control. But these facts will be worthless for the head of the undertaking if he is not conversant with the units of measure allowing him to estimate whether the quantity and quality of the work he produces is below or above the standard.

To be able to manage, close at hand or far away on the basis of reports, it is necessary first of all to set up for each operation, a standard performance. In other words it is necessary to establish in each case "that which represents a good day's work," the classic expression of Taylor and also used before him by Colbert in the arbitration of the strike of the excavators at Nancy.

I shall not dwell upon the means which I use to establish scientifically and for each kind of work, the ideal output which may be considered equal to 100 per cent. They are standards based on time studies. I do say however that before making time studies and setting up standards of production, I standardize first all raw material, machines, methods, and conditions of work according to the wise advice of Taylor, and described by Hathaway.¹

Coordination and Supervision of Work of Several Mills. This standardization of working conditions is particularly important when the point in question is one of the coordination and supervision of the work of several mills, often located in different countries.

The role of general manager is greatly facilitated by the comparison which can be made between orders and net costs in the different plants. There is a very effective reciprocal control and all proficiency realized in one place can be immediately spread elsewhere. One of the greatest advantages of industrial consolidations comes through the reports to small isolated enterprises. But for the reports to be comparable it is necessary that everywhere they be established in exactly the same way. It is necessary to standardize the methods. This is one of the greatest tasks of the general manager and his major personal staff. The standards established, vigilance is necessary all the time to maintain them. The maintenance is more difficult than the setting up and demands an expenditure of extraordinary energy.

Men seem naturally undisciplined and the worthwhile ones more so than the others because endowed with more initiative. If a general manager, having standardized working methods in several plants deviates from a strict control during some months he will find on all sides modifications of the standards, small and large, good and bad, and the output of the different plants are soon no longer comparable.

¹ HATHAWAY, H. K.: "Standards," *Bulletin of the Taylor Society*, October and November 1927.

There must be close to the chief, a bureau of standards, to examine all proposed changes in existing standards, reject or modify the poor ones, adopt and introduce the good, in all mills according to the best method known at the time. This is in a way the "organization of progress."

With reports of operations coming to the chief from all parts and comparable each with the other, and with a theoretical ideal accomplishment, it is bound to be easy for him to judge from a distance the value of the work of all the constituents large and small.

To be able to follow all these records easily it is useful to have them presented as often as possible, in the form of charts. These can be read at a glance, give a synthetic view of the past and oftentimes allow by the direction of the curves, a sufficiently exact estimate of the future. Set down on transparent paper and transmitted in copy to the different directors and superintendents, they constitute without any red-tape, the most valuable medium of competition which the head of an enterprise has at his command.

This is also a means of saying all one has to say in dealing with touchiness. A superintendent of a plant will be hurt and finally demoralized if his chief writes to him repeatedly: "Your output is the poorest of all the plants." On the other hand he cannot be offended at the little black line which will point out to him that he is "at the foot of his class." And if he is truly a man deserving of a position of responsibility he will not cease till his line goes up with the others again.

Eliminating Unnecessary Reports. There is a danger to avoid in the organization of the remittance of reports: that is that their preparation demand so much time and work that the normal march of work is hindered or a special, expensive personnel is required. It is this fear which makes many industries hesitate to adopt scientific methods. Good sense and experience allow the chief to keep perfectly informed without converting his plants into paper factories. For example, each plant has charts¹ showing at each moment the probable date of delivery and the work in store for each loom. These charts constitute the basis of planning. If he wishes to follow the progress of operations in all the plants, the chief ought then to see these charts at least once a week and in all the plants on the same day and at the same hour. At first glance the problem seems unsolvable; in reality the solution is most simple. Each plant has a small photographic recording apparatus. In all the plants a photograph of each chart is taken on a certain day and at the same time fixed for all. These negatives are quickly developed and leave the same evening by letter for the general manager. There a simple projection lantern projects them unmagnified, on a screen, and the chief can, at a distance, follow in the smallest detail, the progress of the organization of work in all the plants which are under his direction. It takes only a few minutes to make the negatives. Consequently no increase of work for the employees is entailed and the quick transfer of very detailed papers, otherwise untransferable, is effected at little cost. As for the director of planning, who knows that the account of the errors of his subordinates will thus be transmitted to the head of the enterprise, he will make every effort to do his work very exactly.

¹ LANDAUER, EDMOND: "The Control of the Factor 'Time' in Production," paper presented at Scientific Management Congress, Rome, 1927.

The planning charts are indispensable in any plant, in order to organize the work rationally. This photographic apparatus thus allows me to "see" from a distance. This same apparatus permits me to see other things also.

If a new building is being constructed or a new machine set up the photographs are taken, and dispatched, each week for the buildings, each day for the machines, so that I can follow the advancement of the operations. Several times I have telegraphed instructions for the correction of errors made plain to me by these negatives. Above all, thanks to this simple procedure and small expense, all those concerned, wherever they are in Europe, feel the eye of the master fixed on them and deny themselves certain liberties and laxities which would inevitably follow if it was not known that I should inevitably be informed.

The reports, standards, controls by comparative charts, by photographs, and by many other procedures prevent wrong-doing for fear of blame or reproach from the chief. But fear alone is an inadequate element especially at a distance. It is necessary to double the rewards of tasks well done. This is the part of the bonuses.

Bonuses. Bonuses aim to inspire each member of the personnel, the most humble as well as the most eminent, to put the greatest efforts and intelligence into his work. According to whether they are well or poorly conceived these can be the best or worst of things. I know of plants where awkward bonus systems have provoked discouragement, sabotage, even strikes.

The most important characteristic of a bonus system ought to be justice. The bonus ought to reward personal effort and that only. Nothing breaks the spirit of a personnel so surely as the concession of rewards which have not really been earned, unless it is the loss of bonuses despite a sincere effort, on account of circumstances independent of the will of the one concerned. This is why I consider as absolutely injurious the participation of the workers and employees in the annual benefits of the enterprise, over which no one, save the general manager, has decisive action.

For each kind of work there must be a special bonus system which rewards or punishes each man's personal action. Thus it is that dyers are interested in the production of the winders which follow them immediately in the flow of work, for the winding will be good more or less according to the care which the dyers have taken in their work. The winders are interested in the production of the warpers for good bobbins make warping easy. The warpers are interested in the output of the weavers, for upon the perfection of their warp will depend a great deal the output of the mill. The weaver receives a bonus on his output, which depends upon his skill and attention to his work. He receives also a second bonus, called a quality bonus, which recompenses him for the perfection of his work.

The foremen, the technical director, receive two bonuses: the first based on the output of the weavers, the second (and most important) based on their quality bonuses; for it is in the perfection of the work that the action of the foremanship and technical direction can be most effectively felt. The chief accountant receives a bonus when the correct monthly balance sheet is delivered within fifteen days after the close of the period accounted for and the bonus decreases in proportion to the length of delay of the dispatch.

By analyzing with care each kind of work one can almost always establish just bonuses which inexorably bind the reward to an effort toward lowering the net cost or toward the improvement of working conditions or of control. Once this connection is well made, the interests of the personnel and of the enterprise become identified and the main cause of difficulties has vanished.

The head of a great and very extensive enterprise finds himself therefore supported by a whole army of assistants who cannot do harm to the undertaking without harming themselves. The incompetents, and the poorly adjusted distinguish themselves by their lack of gain, which immediately provokes an intervention, seeking at first to adjust, then eliminating in the hopeless cases.

The Part of the Managing Director. All the art of direction at a distance consists then in binding the interests of the men to their work, to make known immediately what happens, and to show each member of the personnel that he is one of such an organization that all errors will be inevitably conveyed to the chief. The result of this last is the presence of a permanent morale, in even the smallest corners of the plants, an ubiquity which physically could not be realized.

We have all, when young, read a fable in which the necessity of the eye of the master was emphasized. The great modern industry has not suppressed this necessity but has modified its mode of action. The eye should manage to see from afar and the master to be everywhere. Only scientific organization, well understood, can permit this.

ESSENTIALS OF LARGE-SCALE ORGANIZATION

By W. J. DONALD, *Managing Director, American Management Association*

Probably the most important trend of business is that toward large-scale operation, the success of which is based on the substitution of good management for poor management. We are all familiar with the cataclysmic spread of the consolidation movement during the last few years and while it has temporarily subsided in some degree, we should not reach the conclusion that the trend has ended or in some lines of business even more than scarcely begun.

This development takes two forms. First, there are the various classes of consolidation of companies. Second, there is the expansion of the individual company through natural growth due to good management. Many companies are large because they have had good management and have just naturally expanded. Other companies are large because they secured good management, frequently through merger.

To a very considerable extent, the modern management movement has found its source in the larger units of business. While there are hundreds and thousands of well-managed small and medium-sized companies, nevertheless a large part of the best in modern business administration can be traced to its origin in those companies which today are among the largest because of the quality of management which brought about their growth and size.

Organizing the Management Group. The first essential of large-scale organization has to do with the problem of organizing the management group. This problem appears with special force in most large organizations which come about through merger. The weakness of the merger movement usually appears primarily at the top and is not infrequently the result of a vicious compromise in regard to executive positions aligned with financial control.

We hear a good deal about the dismissal of executives from mergers, executives who were not needed by reason of the merger. It is my observation, however, that as a rule, new consolidations carry a larger executive force, at least for a time, than the affairs of the business warrant and that, in general, there are not enough dismissals following mergers, that too much time and effort are spent in sheer fence building and internal company politics instead of in constructive effort.

It takes time, of course, for the process of the survival of the fittest to work out, but in the great majority of cases the process is inexorable and perfectly legitimate even though often it comes with too much delay.

In general, too much consideration or rather the wrong type of consideration is given to the personnel absorbed through mergers and this same principle usually applies, to some extent, in other large scale organizations. Executives and other personnel not adaptable to a changing situation, especially in the case of large scale operations, are retained through sentiment or a false sense of obligation, not only to the detriment of the company, but also to the detriment of the men themselves who ought to readjust themselves at the earliest possible date and, who, if necessary, should be forced to readjust themselves.

Some of the best merger examples are those in which men who did not fit the new situation were given an immediate release with a liberal dismissal salary or wage and thus given opportunity for a readjustment while there was yet time. It is no favor to any executive or other employee to continue his employment beyond the period of usefulness to a company with the result that the inevitable readjustment is possibly postponed to a time when a complete readjustment is impossible.

Sound Executive Organization. Assuming that large-scale operations will more and more take a major place in business, it is necessary to work out a new technique of management to meet this new situation.

In the course of compromising on executive personnel, there is the imminent danger of assigning to persons responsibilities too large for their range of experience. Executives who have formerly been able to cope with the many details of a small scale operation often find it difficult to confine their thought and activities to matters of policy and principle and to delegate to others the execution of those policies.

On the other hand, there are many cases of the assignment of executives to particular fields of activity only with the result that an executive accustomed to a wider range of activities finds it impossible to leave to others activities over which he formerly had jurisdiction.

The same condition applies to a greater or lesser extent in large corporations which have simply grown or even in corporations which have expanded

gradually to a size of major importance. The pressing situation, however, which the merger movement of recent years has brought about is bringing prominently to our attention the importance of the organization of the upper management group and it has been suggested that the merger movement will force us to develop a new technique of management organization and a new theory of organization or that at least the merger movement will bring about a wider application of principles and practices already effectively adapted to older large scale operations.

Analyzing the Executive's Job and Job Requirements. In the first place, much more careful attention will have to be given to organization relationships and the assignment of responsibilities to executive and departmental personnel. If the fact does not fit all companies, all of us can at least think of some organization of which it is true that executive responsibility and jurisdiction have just grown up without much, if any, scientific consideration of the ways in which responsibilities and authorities should be assigned.

Executives, no less than the worker, have an instinct for workmanship. They get a thrill out of their occupational activities but, in addition, the great majority have a love of power and influence which is much more highly developed than among the rank and file. We are all aware of how a certain type of executive acquires a collection of more or less unrelated activities, for some of which he is not at all adapted, some of which sometimes should be entirely separate. An illustration of the latter is found in those cases in which the auditor is responsible to the executive whose accounts or other transactions are being audited.

What is needed in most companies is a thorough analysis of executive work to be done in terms of the kind of decisions to be made and in terms of the kind of influence to be exercised. It is necessary to distinguish, for instance, between an executive's contribution to a determination of policy in terms of responsibility, or to use an Army phrase, in terms of "command," and his contribution through advice or counsel. The comptroller, for instance, is essentially an analyst of operations and his relation to policy making is essentially that of a counselor. If he is a party to the execution of policies he immediately becomes interested in the interpretation of the results of the execution and loses the desired impartial viewpoint.

Managers of personnel departments who assume responsibility for execution of decisions similarly lose the impartial viewpoint and, worse still, are a party to a division of authority which makes it impossible, or at least difficult, to locate final responsibility.

There is a great need in every organization for a clear cut definition and understanding of the different kinds of responsibility, or to put it in still more generic terms, the different kinds of contribution to the solution of a problem. One contribution may be that of complete line responsibility—command. Another contribution may be that of advice and counsel based upon analysis and comparison. Another kind of contribution is that of persuasion, the selling of ideas and inspiration. Rarely, if ever, are all of these contributions to policy making to be expected of any one executive.

Assuming that we have analyzed and classified executive positions in such a way as to have a job description, the next problem is to classify and group

them in terms of the man requirements of the job so that different kinds of activities may be grouped according to the qualifications required for those jobs. The result is functionalization. The lack of such an understanding of the job requirements and man specifications is probably much more at the root of misplaced assignment of responsibilities than the lack of courage of major executives to deal with such situations as frequently exist. Lack of courage is frequent enough, but lack of knowledge of what should be done and of the basic elements in making a decision in regard to assignment of executive responsibilities is very much more frequent.

Decentralized Responsibilities. The second major essential of large scale organization grows out of the fact that large scale operations almost inevitably destroy the intimate contact of the principal executives of a business with the rank and file. Large scale operations, especially those which have been brought about through merger, are likely to involve several plants, located often at considerable distance apart, a considerable number of branch offices and sometimes more than one sales organization each of them devoted to a different line of products or services. Consequently, it becomes impracticable for a major executive to form judgments regarding the efficient conduct of the business through personal contacts with all units.

The great weakness of large scale operations which have been brought about by merger, particularly for a few years after the merger takes place, lies in the habit of extreme centralization of control of operations. In many cases this habit is simply continued from preceding practice. It is also intensified for a time by what seems to be the necessity for coordinating under standard practices and policies the efforts of those who were formerly competitors or at least executives of other companies.

But the problem of corporations which have grown gradually through a natural process is only partially different, even though its causes may be different and the endless debate regarding the respective merits of large-scale organization, medium-sized organization, and the small type of organization continues to revolve around the question as to whether or not it is possible in large-scale operations to maintain the advantages of small-scale operations while gaining the advantages of large scale operations.

The most successful efforts to reconcile these advantages and disadvantages lies in the direction of the breaking down of operating units through decentralization in such a way as to make individual executives down the line in the organization responsible for an operating unit of a size similar to that in which the chief advantages of small-scale operation appear, providing these decentralized units with facilities that will provide knowledge in considerable degree commensurate with that of the personal knowledge of the manager in the small scale organization.

In the sales organization this means the establishment of branch houses covering territories of appropriate size, embracing a sales force which is within the capacities of a manager to supervise.

In the manufacturing organization it means a breaking down into branch plants and operating units within the plant, each supervisor up and down the organization being responsible for a unit within the capacities of one man to supervise.

The same principle applies in the operation of public utilities, in the management of an office or in the conduct of a wholesaling or retailing business. In retailing, notably, it has been worked out by certain of the more successful chain store organizations.

This decentralization of responsibility is usually accompanied by a large dose of encouragement for experimentation in decentralized operating units, but there are still many large organizations in this country in which practice is standardized at the top and superimposed on the organization with little or no consultation upward from the bottom or inward from the territories.

This comment does not in the least suggest that top management should not actively coordinate the activities of decentralized units or particular lines of activity within the company, but a program of standardization of operations of branch offices, or agencies if you will, which puts a blanket on all independence of thought in the units is almost certain to be the death of progress and destructive of that development of executive material without which men will not be available for executive promotion.

A program of training of salesmen, for instance, which is so standardized as to leave nothing to the ingenuity and constructiveness of branch managers and agency managers may be good at the outset, but it will be dead in a few years. A program of standardizing branch office operations as regards office personnel, office records, etc. which clamps the lid on experimentation will destroy the initiative of executives and stifle the development of methods which must be continually improved.

Decentralization of responsibility, while it lacks some of the advantages of complete standardization of operations and while it introduces an element of continual growing pains, nevertheless, has the vast advantage of creating a point of view and a spirit out of which come constantly improving standards of operation which may be seized upon here and there for adoption or improvement throughout the whole organization.

As a matter of fact, there is even a strong tendency toward the decentralization of staff activities by reproducing headquarters staff departments in various operating units such as in branch factories or district sales offices. Branches sometimes have their own personnel departments, office planning departments, etc., responsible directly and only to the manager of the branch.

There was a time when one could find, and still there can be found cases, in which staff departments attached to district branches reported to corresponding staff department managers at headquarters rather than to the manager of the operating unit, but this today is rare. The relationship of the staff department at headquarters to the corresponding staff at a branch is, or ought to be, a relationship of intercommunication and education and in no way should the headquarters staff department exercise command over corresponding departments at branches.

In many quarters there has grown up a conflict between the necessity of decentralization of responsibility combined with accountability and that part of functionalization which is represented by staff or facilitating departments and in most organizations that conflict has yet to be faced and the problem solved. The solution is to be found in the determination of stand-

ards of operation which may become a basis by which top management may measure the effectiveness of decentralized operations or, to put it another way, for measuring the effectiveness of executives who assume responsibility for unit operations in a decentralized scheme of organization.

This type of decentralized organization facilitated by staff departments has the great merit of providing for locatable, because undivided, responsibility, a condition which develops potential executive capacities. Under it, the effectiveness of executive action can be measured not only because there are no cross-currents of authority, but also because standards of operating effectiveness have been set up and adopted as a program of operation. Under it also, executives gladly assume responsibility.

Experience and responsibility are great teachers, despite the prevalent idea that we can learn more economically second hand. Passive study does not of itself produce executive material. Taking orders from others does not produce the best executive material. Accepting or using the proper kind of advice and help without abdicating responsibility does produce executive ability and produces it more effectively in most cases than if no staff departments capable of helping to determine standards of operation were available.

Establishing Standards of Operation. Small-scale operation of business usually required of the business executive more capacities than it is fair to expect of any one man. In a small manufacturing organization the president or general manager, more likely the owner, is in effect not only president and general manager, but also treasurer, works manager, sales manager, and accountant—usually a very poor accountant.

In a medium-sized business the president, who is general manager, acquires a treasurer with capacities necessary for the job. He acquires a general sales manager with the necessary abilities. He acquires a production executive, if that is his line of business, with the necessary training and experience. He usually acquires an accountant who at least can help him to hold an inquest on the business. In such an operation, however, standards of effectiveness are usually a matter of guess work and opinion with its attendant injustice of judgement and uncertainty of results.

The more the organization grows in size and the more the principle of decentralized responsibility is established, the more difficult it becomes for the major executives to appraise the quality of the management of decentralized units. The solution of this problem lies in the setting up of standards of operating efficiency, standards that, of course, change from time to time as external business conditions change, as technological conditions change and as the efficiency of the organization changes.

There are, of course, a great variety of operating standards which may be made the basis of judgment as to the quality of management of operating units. Just a few of them may be mentioned as follows:

Standards of output for various classes of office workers.

Standards of requirements for jobs to be filled: clerical, agency, supervisory, and others.

Standards of production for branch offices in terms of economic conditions of the territory and in terms of current business conditions and terms of products or services to be sold, etc.

Standards of expense per unit of business sold.
 Standards of returns on investment.
 Rates of pay for units of work to be done.
 Time required to perform an operation: time study.
 Method of performance of an operation: motion study.
 Standards of cost for production, sales, clerical, and other operations.
 Standard ratios between total volume of business and capital investment.
 Standard ratios between current liabilities and current assets.

This list of standards might be multiplied at great length. Enough illustrations, however, have been given to illustrate the principle involved, namely, the necessity of setting up standards against which operating results may be measured as a basis for permitting major executives to determine the relative efficiency of the operations in various units and as a basis for discovering weak spots in the organization so that attention may be directed to the proper point of attack.

Providing Staff Assistance; Facilitating Departments. The necessity for setting up standards of operation in large-scale operations organized on a decentralized plan is the chief factor which has brought about the establishment of the many staff or facilitating departments with which modern business is often encumbered and by which it should achieve new standards of results. Among these departments are: accounting, including cost accounting, departments, budget departments, personnel departments, office standards departments, statistical departments, production control departments, time study and rate setting departments, sales research and sales quotas departments, etc.

Primarily, the object of all of these departments is to assist management in setting up standards of operation and standard methods for the various units in the operating organization. The process of setting up those standards and of getting operating executives to use those standards effectively are both, to a considerable extent, an educational and training process. If the standards of efficiency and the standard methods are developed in an atmosphere of cooperation with the line organization and in an atmosphere which is constantly being encouraged on the part of the line organization, the constant setting up and the constant revision of standards is of itself an educational process which is carried on by the staff organizations that we have mentioned. But probably the greatest internal organization problem current in business lies in the field of the relationship of the various new management specialists to the rest of the organization. One can illustrate best possibly by reference to two or three particular types of staff men.

We are all familiar with the extent to which American business corporations have established personnel departments. They have had a curious history. At first, many personnel departments were established with the idea that they would take over the entire personnel job on the assumption that the personnel job was being centralized. This found expression in the idea that all hiring and firing of the rank and file should be the responsibility of the personnel department. In some cases at one time they even decided on all salary increases, they undertook to rate the entire personnel of the organi-

zation and there were even eager claims for control of the executive personnel situation well up into the organization.

Some departments claimed, and, in some cases, received a good deal of authority in the sense of command. Many of them exercised more authority than had been assigned to them. They assumed a position of "command" as distinguished from the function of "facilitation." Supervisory heads of departments throughout the organization at first resented this condition but later acquiesced because that type of organization naturally produced a division of authority in which could be found exemption from complete responsibility.

The personnel movement at the end of the war was full of the most grotesque ideas about the authority of the personnel department and about the character of the responsibility of the personnel department. One form in which this idea appeared was the designation of heads of personnel departments as "personnel managers," an outcropping of an unsound idea which I have always regretted to observe wherever it appeared. The personnel officer of a company does not manage the personnel of the organization with the exception of the personnel within that particular department itself.

Words and phrases are great makers of the ideas for which they stand and it is my opinion that many a personnel executive handicapped himself and his work by seizing on or accepting a title which induced in his own mind wrong thinking regarding his relationship to the rest of the organization and induced in the minds of others a resentful or contrasuggestive attitude toward the personnel department.

We have come to realize that the personnel job is the job of every department head or supervisor from the lowest rank up to the president. The best personnel and industrial relations men that I know claim no authority whatever, though they might claim "control" in that highly specialized sense of staff influence through knowledge of the facts and through persuasion and advice.

We have come to learn that we cannot hold supervisors of any rank responsible for operations unless they are responsible for their personnel, including a final decision as to employment and power of dismissal at least from the department and, within the range of policy, decision as to salary increase.

With the recognition that the personnel job is every supervisor's job has come also the recognition that the function of the personnel department is that of a "facilitating" department and that it is not an operating department.

We might illustrate also by reference to office planning departments, many of which have come into existence. There are those who argue for responsibilities and authorities for such planning departments similar to the authorities and responsibilities formerly claimed by personnel departments. They assume complete command, for instance, over offices of particular divisions of a company's operations. They assume responsibility possibly for determining and controlling the volume of work to be performed and for controlling the flow of work between departments.

There comes to mind an assistant actuary with a working force of well over two hundred within his own special actuarial department, a working force including, obviously, quite a number of supervisors. One can well

imagine problems of supervision, office layout, problems of routing of work, problems of control of output of clerks within the department, and problems of control of volume of work in such a fashion as to regularize the flow of work, etc. which come up in that department. One cannot imagine any office planning department undertaking to solve that problem in and of itself without the most serious disturbance and possibly destruction of morale within the department and opposition and caustic criticism by the department head himself. One can imagine a planning department offering its services to that department or one can imagine a planning department being sought out by the department head for assistance in solving the problems which may come up from time to time.

A department head, with intimate knowledge of his job, may achieve great improvements that would not have been made to the same extent without the help of an office planning department, help which should represent a detached point of view. The office planning department can have a perspective of the relationship of a particular division to other departments which the department head could not be expected to have in as great degree.

This brief discussion serves to illustrate the facilitating advisory relationship of office planning departments toward the rest of the organization, a relationship which leaves responsibility for results where the function of command is exercised but a relationship which provides those outside points of view, and often technical help without which the same results could not be achieved.

We have referred already to the comptroller, or to use a term of more universal meaning, the head of the accounting department. In manufacturing and in other lines of business, the function and the relationship of the comptroller to the rest of the organization are in a state of much misunderstanding and are subject to a good deal of debate. There is even a dispute over the proper spelling of the term, but the important issue is the question as to whether or not this new executive called the controller has the responsibility for making decisions as to what shall be done: whether an executive should not, may not, or ought to spend.

This question was once raised with a comptroller in approximately the following words, "I see you spell your title 'controller.' Does that mean that you control, or does it mean that you analyze the operations, present your analysis to the operating executives, and leave to them the responsibility for decision?"

This particular comptroller answered, "You bet I control."

The question left something to be desired because there is a difference between control and command. Control may be exercised not only through command, but also through advice and counsel, through knowledge of the facts, through persuasion and even, for that matter, through the influence of personality, but a very hazy line is drawn in many cases between control and command and it is very easy to pass through that line without observing that the line has been passed.

This whole question raises the debate as to whether or not heads of accounting departments, more generally called comptrollers, should reach conclusions and express opinions as to what ought to be done. There are those who

believe that such conclusions and opinions if acted upon or if not acted upon will thereafter warp the impartiality of the analytical work of an accounting department and destroy the open-mindedness of the comptroller and probably build up a counteracting attitude among operating executives.

Of course, the reason that many accounting departments have assumed responsibility closely akin to the function of command lies largely in the fact that altogether too many, one might say the great majority of, operating executives know so little about accounting, accounts, and statistics that they are unable to use accounting and statistical data properly to make operating decisions. Failure so to do almost inevitably leads a major executive to rely too much on the judgment as well as the analytical ability of his accounting department and too often operating executives discover that the situation which has thus arisen offers them a beautiful alibi for operating inefficiency.

This problem of organization will not have been solved until operating executives from top to bottom in proper degree have acquired a sufficient command of the utilization of accounts and statistics to permit them to assume a responsibility for decisions with the help of accounting and statistical data. When that period has been reached, it will have been recognized that the accounting department or the statistical department is a facilitating department, that its head does not exercise the function of command in any degree except within his own department and that it exercises the function of control only through knowledge and presentation of the facts and possibly through advice and persuasion.

"Functionalization" Defined. Functionalization in the proper sense of the word means organization to provide for the execution of responsibility by persons having the requisite qualifications for those responsibilities. The large scale operations which have brought about the introduction of specialized departments have quite obviously required a considerable degree of executive functionalization, to use a much abused and a much misunderstood term.

The setting up of a personnel department, an office planning department and similar departments does not, in and of itself, constitute functionalization, though the term functionalization has often been used to refer primarily to the setting up of such staff or facilitating departments.

Functionalization does include the setting up of departments which exercise an advisory, research, and facilitating function, but functionalization also includes the organization of functions that are in the nature of command such as the organization of the sales department or the organization of the treasury department.

It includes also, for instance, a clear-cut determination of the respective duties of the chairman of the board and of the president if there be both in an organization and the job of functionalization is not complete until the groups of activities based on similarity of executive requirements are paralleled by executive promotions or readjustments that place in such positions men qualified to exercise the functions.

Incentives for Executives. The advantages of sound executive organization at the top combined with decentralized responsibility and with facilitating services which help to establish standards, no matter how well worked

out, will fall short of the best results, however, unless the compensation of executives up and down and back and forth across the organization is so arranged as to place a premium not only on individual effort, but also on coordination between departments and cooperation between line operating executives and department heads and the heads of staff or facilitating departments. The injustice or unfairness of the compensation of executives, however, unintentional, can destroy a large part of all of the values that may be achieved through other organization principles and policies.

The principle of incentive for executives can, however, take several forms. It is still true that the great majority of corporation executives other than owner-managers receive their compensation in the form of salary only and even owner-managers usually receive a salary, a part of their income taking the form of a somewhat speculative return on the investment, usually inaccurately called "profits."

It is not our purpose at this point to debate the relative merits of salary versus extra financial incentives as methods of compensating executives. It is sufficient to point out, however, that a salary basis of compensation will have become a true financial incentive when the organization adopts the principle of revising salaries on the basis of known results of operating executives compared with operating standards set up for the organization by top management with the help of staff assistants and the information they provide and with the knowledge, understanding and concurrence of the operating executives.

A district sales manager who can produce results more favorable than estimates which have been concurred in not only by the chief executives, but also by staff departments and by himself, has, other things being equal, a just claim for upward salary revision which no wise organization would withhold. The standards against which his operating efficiency may be judged may include a wide variety such as number of orders secured, total dollar value of orders secured, standard sales costs such as office expenses, traveling expenses, etc. It may also include collection standards, standards regarding the size of order, standards for determining whether or not the whole line of products or services is being marketed.

Standards for salary for a production executive may include standards of labor turnover, standard costs of production, standards for waste, standards for inventory of raw materials and goods in process, or, depending on the situation, a variety of other standards of manufacturing operation.

The point is that salaries without extra financial incentives can provide a thoroughly sound financial incentive for operating executives provided the standards are properly set, all necessary standards taken into consideration and provided the operating executive fully understands and concurs in the standards which the organization sets up; but it should be pointed out that an effort to compensate executives in any form which takes standards into consideration places on management a serious responsibility to establish standards that are reasonable and fair else the use of those standards for helping to determine compensation may become a destructive and demoralizing rather than a constructive influence.

But the trend is very distinctly toward the placing of executives on some form of extra incentive basis of compensation, a trend which is very much facilitated, not only by decentralization of responsibility, but also by the current trend of setting up of standards of operation. The form of extra incentives for executives varies greatly between different companies and in many companies it varies for various classes of executives within the organization, one method being used for executives high up in the organization and another being used for executives in different branches of the organization such as manufacturing, sales or in the office.

Some plans of extra incentives for executives put a premium upon cooperation between major executives and more or less take the form of managerial profit sharing in the higher ranks. They are particularly suited to those executives whose work calls for cooperation with other major departments, though the same principle applies at least in some measure throughout the entire organization.

Other plans of extra incentive lay emphases on the securing of results in excess of standards set up for the particular operating unit and are particularly applicable to executives who have largely within their own control the operations over which they have jurisdiction.

Some plans provide for a guaranteed salary above which a bonus is paid. Others provide for what in effect is a drawing account against a total volume of compensation based entirely on operating results.

Some plans would seem to assume that standards of operation are hard to set and therefore establish a basis of compensation on broad general terms rather than on results in excess of specific standards. Other plans assume the careful setting of standards and provide for extra incentives based on comparison with specific standards or combinations of standards.

The trend is very distinctly toward the careful setting up of standards, the careful measurement and recording of results and, so far as possible, compensating the executive on the basis of the results of his decentralized operating unit.

Developing the All-round Executive. The major problem of large scale organization is one of the finding, usually through development, of a group of large-scale executives, men with a broad, comprehensive point of view. There are certain lines of emphasis in executive capacity which in most fields of business are today essential. These lines of development are usually paralleled by corresponding staff departments, the purpose of which is really twofold:

1. To help develop standards of operations.
2. To help develop executive capacity.

Assuming that we have the proper sales executives, the proper accounting executives and the proper financial executives who major in their respective fields, nevertheless, there are certain phases of business management which are or ought to be the property of every executive and every supervisor in the company. To these we wish to return briefly.

First, every executive and supervisor must become more and more a personnel man. The day has gone by when personnel problems are being

solved by personnel departments alone. Personnel departments do make it easier to solve personnel problems. More particularly, they are designed to develop the capacities of executives to deal with personnel problems either in terms of standard practice or to improve the standards of personnel practice and policy by searching out within the company and elsewhere new methods which may be developed in decentralized units in an atmosphere of warmly encouraged experimentation.

Second, let us return for a moment to office management problems which appear not only at the headquarters office but also in agencies and branch offices, in the treasury department and in general administrative offices. No office planning department can solve all of the problems. The best practice lies in developing the office management capacities of all supervisors and all department heads whose offices contain such employees or office operations.

Third, planning a program for an operating period must become the accepted practice of all executives in an organization. Planning this program is budgeting. Budgeting is not the setting up of a set of expense maxima. Estimates often should be exceeded as conditions within an operating period change. Similarly, in many cases estimates should not be used up simply because they have been approved.

If planning a program in the form of a budget is to be participated in by all classes of executives, the essential requirement is that those supervisors and executives shall become accounting and statistical minded, at least sufficiently so to permit them to interpret accounting and statistical data as a basis for operating decisions.

It is no part of a budget director or whatever he may be called to decide that expenditures cannot be made because the estimated maximum has been reached. That responsibility of decision should rest with the department head, or his superiors, if necessary. It is the budget director's responsibility to make the comparisons and to provide the necessary information on which decisions can be made wisely.

Fourth, while many lines of business will undoubtedly set up public relations departments, yet no public relations department can possibly solve the public relations problems of any line of business. The establishment of a public relations department is only the beginning of a public relations program. The problem will never be met and solved until every executive takes his proper attitude toward the public and toward service to the public and until the rank and file of the personnel through attention to the subject by supervisors become public service conscious and effective in their contacts with the public.

While we are accustomed to thinking of certain lines of business as being essentially affected with the public interest, nevertheless, the growth of large scale operations will gradually affect all lines of business with the public interest, possibly not in the common law sense, but, nevertheless, in an economic and social sense.

Finally, if we are to have the kind of large-scale business executives that obviously will be needed and for which there is always a demand, we must develop a new understanding of organization relationships and organization theory. There is need for a clear-cut statement of organization theory, but it is hard to get because executives of even the largest corporations are

not ready to admit that the practice of organization relationships is still far from satisfactory.

One of our difficulties lies in the attempt to transfer to business administration certain doctrines of governmental structure which are the cause of those conditions in governmental circles in which many of us, as citizens, find no comfort. We refer particularly to the theory of checks and balances, and the theory of division of powers between legislative and executive bodies. Both of these are too easily translated into a theory favoring division of responsibility.

We do not propose to debate the merits of our plan of governmental structure in the federal or state field, but it is safe to say that, when city after city, some 500 or 600 of them, have adopted the city manager plan of government embracing the principle of locatable, because undivided, responsibility, as supposed to be found in business—this is no time at which to be incorporating into business a doctrine from which our municipal governments are trying to escape through the adoption of the city manager plan of government.

Large scale operations will force upon us intensive study of the problem of organization, both in organization relationships and organization theory. Without it, attention to personnel, the setting-up of the personnel department; attention to office management and the setting-up of office planning and service departments; attention to budgeting and the setting-up of a budget department; a better understanding of accounts and statistics and the setting-up of corresponding departments; more attention to public relations and the setting-up of a public relations department will not solve the problem of large-scale operations.

In conclusion it may be said that the essentials of large-scale organization are:

1. Setting up the managing group in terms of jobs to be done and in terms of the man requirements for those jobs.
2. Decentralization of responsibility in operating units.
3. Setting up of standards of operation.
4. Establishment of staff departments, partly to help establish standards of operation and to compare results with those standards and, even more important, to help develop executive capacities.
5. Adoption of the principle of incentive for executives.

Clear-cut and scientific assignment of responsibilities, the decentralization of those responsibilities, the setting of standards of operations and comparison against those standards, these combined with the principle of incentive offer opportunity for development of executives through experience and initiative. They provide for the discovery of successful executives through comparison against standards. In other words, they provide opportunity for encouragement to and for discovery of efficient executives and they do it in terms of those organization principles without which large scale operations will be of doubtful economic or social merit.

CHAPTER II

THE TECHNIQUE OF MANAGEMENT REQUIRED TO MEET RAPIDLY CHANGING CONDITIONS

BY PEARCE C. KELLEY, *Assistant Professor of Business Administration,
School of Business, University of Utah*

An old sage once remarked that if there was anything about business that remained constant it was the fact that conditions were constantly changing. Today, it is the rapidity with which these changes are taking place, and how the situation can best be met, that is occupying the attention of business executives. It is a big subject, and one deserving of considerable attention. Wide variations exist between different industries, and the importance of the problem will vary accordingly. In one case the emphasis will be upon meeting rapid changes in consumer demand, style changes, or new demands. In another case the point of greatest complication will be meeting rapid changes of a technical nature, discoveries of new substitute materials, improved basic processes, or new and greatly improved machinery and equipment. Considerable variation likewise exists with reference to the degree of rapidity with which conditions change. Certain industries, such as the radio industry, have been characterized by very rapid changes. In other industries changes have taken place at a more leisurely rate, resembling more closely the regular natural rate of growth or expansion in the industry. In general, however, the trend in recent years has been toward both an increasingly rapid rate of change, and the spreading of the area affected by rapidly changing conditions to more and more industries, until today, it is not safe to consider any industry immune from this phenomenon. While this is undoubtedly true, it is also true that a corresponding development has taken place in management's ability to meet rapidly changing conditions. Not only has management technique in this direction been greatly improved in recent years, but also many of the changing conditions are becoming more rational, or at least better understood, and consequently within the realm of possible forecasting. So we have the business paradoxes today, of industry desiring stability, yet promoting change; of conditions changing more rapidly with a wider area affected, while within the system the ability to meet the situation has correspondingly improved. The poison always has its antidote, if only it can be found. The purpose of this paper is to help to find the antidote for rapidly changing conditions. It may seem at times to deal with rather obvious considerations, but it is often these more obvious things that are neglected in the rush of daily routine unless specifically provided for. No claim is

laid to a comprehensive treatment of the subject, and the emphasis is placed on presenting a technique of rather general applicability. It is hoped that it will at least succeed in stimulating further discussion of the problem.

How Management Meets Changes. To keep a business in tune with rapidly changing conditions is a major responsibility of management. If management were always purely personal, and could anticipate the change well in advance, the problem could hardly exist. Neither of these assumptions is true, however, under ordinary circumstances. Management is not purely personal, except possibly in a one-man business, but works through an organization, and often an elaborate and rather rigid one at that. Nor can management be said always to know sufficiently in advance which way the cat is going to jump. Many of the most perplexing problems of business would immediately vanish if such a utopian situation could be established.

A recent survey conducted under the writer's direction showed that there are three general methods used by management in meeting rapidly changing conditions. They are the following:

First, by following what might be called an *opportunistic* policy. No special provision is made to cope with the problem. Adjustments are made in the business whenever knowledge of change happens to come to the attention of those in charge, and it appears to them to be advisable to take some action about it. This, of course, is hardly a desirable or safe policy to follow, even in the small or fairly stable business.

Second, a large number of firms have placed their reliance in the *trade association* to keep them informed on changing conditions and to suggest remedies needed. Adjustments in their organization are usually made only after the need for them has been pointed out by the trade association, and sometimes not until pressure of the changed conditions makes such adjustment imperative. Something will be said later about the excellent work being done by trade associations in this direction. At present it is sufficient to note that neither of these plans, taken by itself, is entirely satisfactory. Assistance from the trade association should certainly be utilized, but it should fit into a broader plan of which it is only a part, even though a very important part.

Third, in a few cases, but the number is rapidly increasing, *definite provision has been made to meet this problem and a carefully worked out technique developed*. Naturally, this holds true for the more progressive, and usually the larger, firms, as well as for firms in the industries that have been most subject to the influences of rapidly changing conditions. The technique suggested in this paper is based primarily on practices found in this group of concerns, with such modifications as seem desirable to emphasize certain underlying principles and to make it of more general applicability.

In order to meet changing conditions, management must be aware of the changes in time to make the necessary adjustments to meet them. This requires proper utilization of sources of information concerning changes, coupled with a healthy organization sensitive to change and flexible enough to permit rapid adjustments to the new conditions. Before taking up in detail a discussion of the necessary technique, it may be well to state briefly the three major requirements. They are:

1. A fact-founded operating organization.
2. Anticipating and forecasting rapidly changing conditions.
3. Maintaining a sensitive and flexible organization readily amenable to change.

An elaboration of these three requirements will occupy the balance of this discussion.

A FACT-FOUNDED OPERATING ORGANIZATION

The first requirement of management technique is, then, to have a fact-founded operating organization. This is true regardless of the size of the business or conditions under which it operates. The action taken by an individual business at any time is governed by two groups of factors: first, *the personal factors, calibre of executive personnel and executive decisions*; and second, *impersonal or organization factors, such as policies, standards, written or printed instructions, and budgets or operating schedules*. The importance of alert, well-informed executives cannot be overemphasized. Fact-founded executive decisions are the very cornerstone of management. Statistics, and all other information, is only an aid to sound judgments by executives. The use of impersonal factors as action guides is in line with operation on the exception principle of management and needs no justification. When originally formulated, policies, standards, and other organization factors should be based on a careful study of conditions. As long as conditions remain the same they serve to guide ordinary activities of the business, calling for higher executive decisions only to care for the exceptional cases as they arise. With both groups of factors, however, a real danger exists in a failure to keep them in tune with change, unless the necessary steps are taken to accomplish this result. Habit, custom, inertia, and lack of prompt and reliable knowledge, are some of the chief forces retarding adjustment on the part of the personal element. Failure to make definite provision within the organization for keeping the impersonal factors up to date accounts for the major difficulty in this group. This implies making the necessary provisions for securing and utilizing information on rapidly changing conditions.

To keep management aware of changes a regular flow of immediate and reliable information must be established from the sources of information deemed to be reliable, to the points of utilization of this information within the organization. This is required by executives in making decisions in routine matters, as well as in advance planning and operating activities, such as in buying style goods, and similar work. It is necessary in relation to the impersonal factors, partly to insure their proper application as illustrated by the need for a knowledge of competitors' prices in enforcing a certain price policy—and partly to make possible an evaluation of the present desirability of these factors. Policies, standards, and other organization factors are reliable guides only when the conditions affecting them are essentially the same as when these guides were formulated. A change in conditions may render them obsolete or inadvisable or may necessitate merely a quantitative adjustment, as when a master budget is altered because of sudden changes in purchasing power or demand of customers. In any case it is necessary to know what changes are taking place to be able to judge the

present value of the action guides under existing conditions, and to determine what adjustments, if any, may be needed.

In order to keep posted on conditions, it is necessary to know what changes to look for, to know where to look for information about them, and to provide a regular flow of this information from its source to points of utilization within the organization.

What Changes to Look For. The first consideration is to know what changes to look for. At the outset it should be noted that there are many different kinds of changing conditions to be encountered. In most cases there is a fairly regular change taking place, interrupted at times by somewhat irregular variations. In regard to economic and social conditions there is a sort of normal healthy rate of growth or unhealthy decline to be encountered, which may be temporarily accelerated or retarded by such phenomena as the business cycle and seasonal variations. These changes can usually be anticipated under ordinary circumstances and provided for by alert management, at least as well in one business as in another in the same field. Except in extreme cases, they do not come in the category of rapidly changing conditions, although they may enter this classification at any time and consequently must be provided for. The nature of changing conditions that are the primary concern of this paper, such as new inventions, new products, the rise of new industries, growing importance of style and color and its spread to new fields, demand changes, creative obsolescence, new methods and types of organization are well known.

Where Will Rapid Changes Occur? A survey of the organization should be made to determine the various factors subject to change, those most susceptible to rapid change, and at what points rapid changes may prove of vital importance to the organization. To do this it is desirable to have some means of assuring that all factors will be considered, and then their relative importance can be judged in the light of the particular circumstances of the case. This can be accomplished in several ways. *One method is to consider the action guides* previously discussed, determine what changes would affect them, and the nature of information needed to keep them in tune with changes. Whenever operating schedules—sales, production, or financial budgets—are used, it is customary to provide for keeping them adjusted to changing conditions. The same principle should be applied to the other action determining factors. Thus, each policy, standard, operating schedule, etc. would be considered from the angle of what and how changes would affect it and what information should be obtained, both to enforce it, and to determine when it should be adjusted. Then, for the personal factors, the type of information required by each executive should be determined so that it could be furnished to them. To some extent this method of procedure is used by nearly all firms, although it may not be carried out in the methodical and comprehensive manner just described. Our survey showed that in organizations having a centralized division concerned with furnishing information about changing conditions the regular practice is to solicit from executives the type of information they desire. In fact, in most cases the procedure went farther than this and attempted to anticipate the information that each executive would need, to be able to furnish him with it.

A second method is to consider each of the major functional divisions of the business and build the system of intelligence along these functional lines. Thus, in the retail field, information on changing conditions would be grouped according to whether it related to the merchandising, store management, control, or publicity divisions, assuming these to be the functional divisions used. In a manufacturing concern, production, distribution, finance, and the various facilitating functions would form the basis for classification. The advantages of this approach are many.

1. In the first place, each major functional division represents a fairly homogeneous group of activities affected primarily by changing conditions of a particular type. For example, the production division is concerned with the application of motion to materials and is affected by technical changes in materials, machinery, and equipment, and production methods or processes; whereas the distribution end of the business is concerned with moving goods to the customer and is affected by changes in consumer demand, the structure of the distributive system, and similar conditions. It is of course not meant to imply that production and distribution can be considered as distinct and unrelated divisions of a business. The two are interrelated and must work together.

2. The second advantage of this plan lies in the fact that the business is already organized and operating according to these functional divisions, consequently it should be guided in terms of these operating units.

3. A third advantage is that techniques of management of the functional divisions, and specialized knowledge of each, have already been built up, such as sales management, scientific purchasing, and production management. This knowledge might as well be utilized. That the plan is satisfactory is born out by the fact that it is used by some of the leading management and research groups, especially, but not exclusively, in the retail field.

In both of the plans just discussed some particular business is used as a starting point. *A third plan is to consider the factors common to all lines of business* and determine those entering into the phenomena known as changing conditions. To go back to fundamentals for a minute: every business is endeavoring, under certain social and economic conditions, to provide goods or services to its customers, usually in competition with other companies, and at a price that will return a net profit. In doing this it must work with an organization of materials, equipment, methods, men, and money. One, any, or all of these factors—economic and social conditions, product or service, customers, competition, price, materials, equipment, methods, men, and money—may vary and make adjustments necessary by the company to meet the new combination of factors. Taken together, changes in these factors make up what we mean by changing conditions. They are the elements common to all businesses in considering the problem of meeting change. Even when one of the two previous plans is used it will usually be found that the changing conditions considered are changes in one or more of these factors. Consequently, this grouping, or classification, of factors will be used for illustrative purposes in the remaining discussion of what changes to look for. There is no implication of superiority of this grouping, but like all classifications it serves a useful purpose. The important thing is to conduct

a thoroughgoing survey of the organization according to some comprehensive plan, determine the changes to watch for and the relative importance of each to the particular business under investigation.

Changes Arising from Competitors. In considering the nature of some of the changes to look for, the differences in viewpoint of various readers should be taken into consideration. The discussion is intended merely to be illustrative and not all inclusive. Most of the changes that take place with reference to the product or service will come from competitors. The ingenuity of American business men in developing new products and services in hitherto unsuspected directions is proverbial, and careful watch should be kept for these developments whether they come from competitors or others. As illustrations of new services in distinctly service industries witness the introduction of the "talkies" and later the "pee wee" golf courses in the amusement industry. For new services merely as business getters, recall department store history with its long list of services, and similar cases among the other retail types. As to new products, the radio is probably the classic example. Other changes with reference to products may relate to variety or simplification, characteristics such as quality, design, color, type of container, and similar marks of differentiation.

Changes in Economic and Social Conditions. Rapid changes in economic and social conditions are only too familiar. Mention has been made previously of the changes ordinarily watched for, namely, growth trend, business cycle, and seasonal variations. Additional changes of a local or sectional nature should also receive attention, as well as conditions within a particular industry. These are not usually too rapid to be adequately provided for by alert management, but may become so at any time. One part of the picture, particularly, is deserving of considerable attention. This is to watch the action taken, or policy followed, by certain groups, such as the Federal Reserve Board, Farm Board, etc., which may precipitate a marked and rapid change in economic conditions. The best laid plans of business founded on studies of economic trends may suddenly become obsolete unless the work of such agencies is taken into consideration. Of course a really adequate trend study will take these influences into account. Then there are such factors as new legislation, court decisions, activities of the Federal Trade Commission, Interstate Commerce Commission, and similar bodies to be considered. Changes brought about by a widespread adoption of certain products such as the automobile or radio will often have important implications. And finally, social changes in the nature of changing public opinion, violent changes of an emotional or mass psychology nature should be considered.

Changes Due to Customer. Not long ago some enterprising individual discovered a new force in business, the customer, and since then the wheels of industry have revolved about the changing demands of its new ruler. Today the customer is king. No truer statement was ever made. Consumers' preference, in a buyers' market such as business is in at present, is not something to be toyed with, patted affectionately, and then thrown into the discard, as many companies have discovered to their own sorrow. It must be respected, studied, and catered to. Probably the rapidly changing conditions of most fundamental importance that are taking place today are directly,

or closely, associated with the customer. Someone has well characterized present-day conditions as a "buyers' renaissance."

In taking up a discussion of changing conditions relating to the customer it should be noted that there are at least three distinct groups or classes of customers: *purchasers of industrial or producer's goods or services; commercial purchasers of goods or services for resale; and the final consumers.* Usually customer changes studied in any of these groups will be viewed from one or all of the following angles: changing type and amount, changing status, and changing demands. Management wants to know changes that are taking place in the *type and amount of customers* a firm has. Is the number of small buyers increasing at the expense of large buyers, and why? Or is the reverse taking place, indicating possibly a more economical distribution, or possibly a dangerous concentration of accounts? Is the firm losing or gaining customers, and why? Is the type of customer changing? What will be the probable effect of this change, desirable or not? These and similar questions management should at all times be able to answer. Then changes take place in the *status of customers* that deserve consideration. Changing purchasing power may necessitate changes in price lines or price levels at which the company sells. Changes in standards of living have been taking place more rapidly in recent years, but could hardly as yet be classed as rapidly changing conditions. They may make advisable changes in marketing methods—selling a product as a staple instead of as a luxury—or variations in advertising appeals and media used. More rapid changes in the status of individual customers is likely to take place in regard to items like credit. The numerous safeguards established by business to guard against credit "skips" and bad check artists bear witness to the need for prompt action in dealing with this problem.

Changes in *customer demand* are the ones receiving, and justly deserving, the lion's share of attention today. Demand changes may refer either to the product or to auxiliary services. In analyzing these changes it seems advisable to consider each of the three groups of customers separately. Demand changes from industrial customers often take the form of demands for new types of machinery and equipment to suit new needs, new methods or processes of production, new types of power, and even new industries. In selling to commercial customers mainly auxiliary service demands are likely to be encountered, such as demands for more rapid deliveries, opportunity to get goods in smaller lots, and resale assistance. The first two are manifestations of a phenomena to be considered later: speeding up processes all along the line to keep inventories in the most fluid and flexible state possible. Witness the hand-to-mouth, or small-order, buying policy so popular today. The demand for resale assistance, or selling for, rather than selling to, the customer is indicative of the shifting functions of manufacturer and distributor, the former assuming more of the responsibility for demand creation, the latter concentrating more on the physical handling of commodities. In so far as changing demands of this group relate to the product they are reflections from changes in demand of the consumer, and consequently will be dealt with there.

Any consideration of changing consumer demand must recognize at the outset the tremendous and growing importance of women as purchasers of consumers' goods. Mrs., or Miss, Consumer is the keystone in the arch between production and consumption. Without her support no business can hope to survive in this field. She is the source of more demand changes today than probably all the other factors combined. Consequently her likes, dislikes, and other characteristics will repay careful study. It is no longer possible to initiate sudden style changes and tell the consumer to like it. Rather is it necessary to study her likes and needs, and construct products and services to fit these requirements. Hence the modern stylist, as an integral part of an organization dealing in style goods. What applies to style changes also holds good for consumer preferences for color, line effects or design of product, packaging or container, and types of auxiliary services offered. Today the customer is looking more for total effects than to price and quality, taking these for granted. Witness the popularity of the ensemble idea, the trading up movement, the demand for quality and style at a reasonable price. All these preferences must be given due recognition. It would be difficult to even indicate the numerous ramifications which demand changes may take, but sufficient has probably been said to signify the necessity of giving this point the most careful attention.

New Phases of Competition. Recognition of the need to cater to the customer, coupled with a tremendous increase in productive capacity in proportion to increased demand, have introduced new complications in the nature of changing conditions in respect to competition. In attempting to cater to the customer, to entice her away from competition, or to secure a greater share of her expenditures, business has flooded the market with a never-ending array of new products and services, style changes, novel selling schemes, and no end of variety and change. A new technique, creative obsolescence, has been introduced along side of, and supplementary to, its big brother mass production. Intercommodity and interindustry competition have made their appearance. Consequently, we see the rise of competition of a new type that must be taken into consideration in formulating plans for changing conditions to be observed. Some of the things to be considered with reference to changing competition are: the increase or decrease in its amount and severity; changed character of competition, whether more aggressive or more conservative, more intelligent or blinder competition, totally new competition either from new companies or in the nature of intercommodity or interindustry competition. Another type of change that many companies have experienced is to find themselves competing with their own customers, although this is less likely to be a rapid change excepting in cases of sudden alteration in policy. And finally, changes in competitors' methods and policies in all directions should be constantly observed.

Price Changes. Rapid changes in price are common and must be reckoned with. Change in the general price level, prices of the particular commodity or service, and competitors' prices are the points requiring consideration. Obviously price trends in these items should be carefully followed.

Changes in Materials. Changes in the nature of materials are of great importance in certain industries, and often take place so rapidly as to have

almost revolutionary effects. Witness the rise of rayon, lumber substitutes, rubber and textile substitutes, and the whole procession of synthetic products, utilization of wastes, and by-products. Many industries frankly admit these changes to be the greatest source of trouble with rapidly changing conditions. In fact, no industry today is safe from rapid changes in its basic materials, which may even alter the whole nature of the industry almost over night, force it to seek new markets, develop new uses for its product, or make fundamental changes in productive or distributive processes and methods. Consideration should also be given to changes in sources of supply, quality or specification changes, new uses for old materials, and changes in serviceability of materials.

Changes in Equipment, Methods, Men, Money. Equipment changes, while usually less drastic than changes in materials, may be quite important. In manufacturing they usually center around production requirements, scientific discoveries, new processes or methods, new sources of power, developments of mass production and scientific management techniques, and other production improvements. New and improved machinery and tools should be considered. In distribution, equipment changes converge on the modernizing movement in retailing, and on mechanical or more efficient handling in wholesaling. Style and art factors also enter in to some extent, particularly in the retail field.

Changes in methods and processes are taking place in practically all departments of business. Improvements or refinements in old methods, as well as the introduction of totally new methods deserve attention. New methods of distribution, of advertising, of production, of retailing, and of all activities of interest to a particular business should be considered.

Not much need be said about men as a factor in rapidly changing conditions. It is true that the calibre, education and training, aggressiveness, and similar qualities will vary and may in unusual cases—such as a change in personnel at the head of some agency which has a widespread effect on business conditions—be the cause of rapid changes. However, while this factor is of the utmost importance to business in other considerations, it need not detain us longer in this connection.

The money factor enters in some form into all business transactions. Rapid changes in this factor may be of great significance. Changing interest rates, changes in sources for securing funds, credit conditions, state of the money market, and numerous other things require attention.

Sources of Information on Changes. After a survey has been made and the type of changes to watch for or information about changes required has been determined, the next thing is to locate the sources from which this information may be obtained. This is another subject that can receive but scant attention in proportion to its importance in the present discussion. Since, however, the purpose is to indicate a technique rather than to present an exhaustive treatment of its application, what is given here will suffice for this objective.

Internal Sources of Information. There are two major groups of sources from which management can obtain information on changing conditions, namely, from within the organization itself or from sources external to it.

Within the organization there are numerous sources of recorded information, records and reports of operation, correspondence, etc., which when analyzed will often give notice of changes. A considerable part of the work of certain staff departments, such as the statistical, research, and accounting departments, is concerned with compiling and analyzing this material. Records and reports of operations should be presented to show trends, and whenever possible, in a way to make them readily comparable with data from external sources. In addition to the ordinary company records and reports on operations, much significant information can be obtained from analysis of the company's experience at points of contact with its customers, such as from the salesforce, adjustment or complaint bureau, returned goods records, and customer correspondence files. Another internal source of information is the knowledge and experience of executives. Every effort should be made to utilize this source, and by means of conferences, suggestion systems, or some other method, stimulate an interest on the part of executives to furnish all possible information on changes. However valuable the analysis of internal data may be, it does not tell the whole story. Rapidly changing conditions cannot be successfully watched by this method alone, as they will not be apparent in records of operating results or other reports until conditions have changed sufficiently to cause their effects on the company's activities to be reflected back through these records. It may then be too late to make the needed adjustments. The knowledge of executives may at times be somewhat better than analysis of operating results, but it is never safe to place sole reliance on internal sources of information.

External Sources of Information. The external sources of information are almost unlimited. They may be roughly classified as unorganized and organized sources. Unorganized sources usually require direct collection of the desired information by means of surveys, observation, or other special investigation. However, there are so many organized sources of information in existence today, that, with the possible exception of consumer surveys, the needs of management can be supplied from one or more of these sources. Just as the work of collecting and handling information in the individual business has been largely specialized in certain staff departments within the company, so has this work for business as a whole been specialized and conducted mainly by certain groups which may be referred to as the outside staff of business. There are many of these staff groups; the more important ones for our present purpose are the following:

Trade associations and trade institutes.

Cooperative management and research groups.

Government bureaus and agencies.

Statistical and forecasting agencies.

Associations:

Professional associations: management, etc.

Functional associations: purchasing agents associations, etc.

Universities:

Bureaus of business research.

Individual research.

Chambers of commerce and local associations.

Miscellaneous sources.

Value of Trade Association Work. Trade associations and trade institutes are probably the most valuable all around sources of information on changing conditions. They have largely taken over from the individual business the responsibility of watching for changing conditions, keeping their members posted, and suggesting remedies. All changes of an economic, legislative, social, and technical nature that affect the industry are observed and reported on. Reports are made on general business conditions, conditions within the industry, new legislation and proposed legislation, new inventions, discoveries and progress of technical developments in the field, changing competition and consumer demand. Often style trends, new methods, materials, machinery and equipment, and other topics of current interest are discussed at conventions and reported to members. Nearly all trade associations report on operating results of members. Many maintain complete libraries on subjects of interest to members, such as the library on fermentology of the American Bakers' Association. Some have even added field men to their staffs whose work is to study changing conditions in the industry at first hand and help members in the solution of their problems of making such adjustments as may be needed to meet these new conditions. Market and technical research and trade extension activities have come to be some of the most important activities of this group. In some fields, such as banking and certain retail fields, special committees have been instituted by the trade association for the sole purpose of watching for rapidly changing conditions and assisting members in meeting them.

Cooperative Research Groups. Cooperative management and research groups have been formed by selected groups of companies in many fields, such as the Retail Research Association and Associated Merchandising Corporation in the department store field. These groups usually have a well-organized system for keeping posted on all phases of rapidly changing conditions of interest to members and suggesting, or even dictating, adjustments that members should make. A somewhat similar arrangement consists of the more or less loosely organized tie-ups between manufacturers and their retail outlets. Here information on changing conditions can be furnished both ways, the retail outlet giving the manufacturer closer contact with changing consumer demand, and the retailer securing information of greater value to him because of the pooling of experience from many sources. In addition to these two major types within this classification, there are numerous agreements for pooling information and experience, cooperation in conducting technical or market research, and exchanging research and operating information. All this, when properly handled, can be of immense value in solving the problem of watching for rapidly changing conditions.

Statistical and Other Trade Information. The valuable assistance now being rendered to business by the federal government furnishes an important source of information on changing conditions. Much of this work, such as the Louisville Grocery Survey and National Retail Credit Survey, is instigated at the request of, and often conducted in cooperation with, trade associations in the field. Bureaus and departments, such as the Census Bureau, Bureau of Standards, Bureau of Mines, Bureau of Foreign and Domestic Commerce, Bureau of Labor Statistics, Department of Agriculture, etc., are continually

collecting and publishing information of value in this connection. Publications such as the *Survey of Current Business*, *Domestic Commerce*, *Commercial Standards Monthly*, *Bulletin of the Federal Reserve Board*, and publications of the Federal Trade Commission and similar bodies provide a mine of information for business.

Organizations furnishing statistical and forecasting services concerning general and special business conditions are almost legion. Some of the better known examples of concerns in this field are: the Alexander Hamilton Institute, Babson Statistical Organization, Brookmire Economic Service, Harvard Economic Society, and Thomas Gibson. Many banks, trust companies, and other business firms publish similar studies, such as those of the Chase National Bank of New York, Cleveland Trust Company, Guaranty Trust Company, Irving Trust Company, National City Bank, the Federal Reserve Board previously mentioned, and the various Federal Reserve banks. In many cases the activities of university bureaus of business research include this type of work, especially that covering conditions within the state, as for example, the Georgia Bureau of Business Research, and the Bureau of Business Research of Ohio State University.

Publications of professional associations, such as the American Management Association and others, provide an especially valuable means of keeping abreast of changing methods and management technique, as well as other valuable data on changing conditions. Functional associations, such as purchasing agents associations, credit managers associations, etc., are especially helpful in providing information on changing conditions affecting their respective fields of activity.

The universities and colleges with departments of commerce, economics, schools of business, or similar departments are valuable sources of information on changing conditions. Whenever an organized bureau of business research exists it will care for much of this work. A wide range of subjects is covered by the activities of these bureaus. These may be divided into two general classes: first, reporting data of a regular or recurring nature on general business conditions, conditions in fields of peculiar interest to business men of the state, and of operating results of local business firms, such as data on sales, stocks on hand, rate of turnover, expense items, and a host of similar operating measures of local conditions. These data, along with announcements of special studies, are usually published in a monthly bulletin. Second, special studies of problems of current interest or importance, such as retail mortality, retail practices, credit problems, methods and policies of manufacturing or merchandising of certain commodities, studies of trends in various fields, traffic problems, housing conditions, wage and unemployment problems, and many others. At present there are some twenty-seven bureaus of business research in the various colleges and universities of the country, representing nineteen different states. This is in addition to the institutes and foundations located at many universities and also concerned with research on industrial and economic problems. About half of the university bureaus of business research publish a bulletin, or similar publication, at regular intervals, in addition to the publication of reports of special studies. The business located in a state having an active university bureau of business

research may obtain valuable assistance in meeting changing conditions by cooperating with it and utilizing its services. In addition to the work of the bureaus of business research, many valuable studies are made on changing conditions, trends in the changing factors, and similar research topics by individual members of the faculty and graduate students.

Chambers of commerce and local merchant and manufacturers associations usually provide information on local developments and changing conditions of a nature pertaining to basic industries or fields of the locality. Of course the state and national associations in this group cover problems of more general interest, but are too familiar to need further consideration here. Numerous other sources could be mentioned, such as trade journals, newspapers, clipping services, service bureaus of manufacturers and wholesalers, market research agencies, style forecasting agencies and others which will no doubt occur to the reader. Enough has been said, however, to show that there are plenty of sources from which information on changing conditions can be obtained. The real problem seems to be the effective utilization of this material.

Provision for Use of Information on Changes. With a knowledge of what changes to look for and where to secure the necessary information determined, attention may be directed to making provision for a smooth flow of this information from its source to the various points of utilization within the organization. That is, definite responsibility should be established for securing the needed information and routing it to executives or committees according to their needs. This is a staff function and is usually performed by one of the staff departments. It is a function distinct from that of utilization of the information by line executives, either in carrying on their regular duties or in making adjustments in the impersonal factors required because of changed conditions. Nevertheless, it is so closely associated with adjusting the business to new conditions that both problems will be somewhat merged. The importance of following a systematic procedure in handling this activity would be hard to overemphasize. It is needed to insure that all information required is obtained; to insure a proper distribution of this information to those who are to use it; to relieve line executives of the responsibility of this staff work; to insure prompt notification and speedy action when required; to eliminate waste motion and duplicate work; to avoid overlooking warnings of changing conditions and to make certain of proper interpretation of trends and unusual conditions; and finally, to insure a proper utilization of the company's organization, and to make a knowledge of changing conditions available to all members of the organization.

Decentralized Plans. Our survey showed several plans in use for handling the gathering and using of information on rapidly changing conditions. One group of plans operated on the principle of decentralized responsibility. Three characteristic plans were found in use here.

1. In one, each department head and other executive concerned was left free to secure his knowledge about changing conditions wherever he could. In some cases trade journals were subscribed to and circulated among executives, but no additional provision was made to keep them informed.

2. A second plan was to hold frequent meetings of executives, department heads, field men, and others, to discuss changing conditions and adjustments that might be needed.

3. The third plan was to place responsibility for supplying information with the various functional divisions of the business, primarily the research and statistical departments, control or accounting division, sales division, and production department. Assistance from outside specialists was also used. Information from all of these sources, together with recommendations for adjustments needed, was furnished direct to a committee on adjustments, and the latter made the final decision on what action should be taken.

Centralized Plans. The plans which operated on the principle of centralized responsibility for collecting and distributing information relative to changing conditions either centralized the responsibility for this function in a division of one of the cooperative groups, or in some department within the business. This was also handled in three different ways.

1. According to one plan a special committee of the trade association, a sort of analysis and research committee assumed the responsibility for keeping posted and recommending adjustments needed to members. This was found in the banking and other fields. Suggested adjustments are not compulsory for member companies, although the advice of this committee is highly valued and usually acted upon. The committee has the definite responsibility for collecting all information on changing conditions and keeping member firms posted. Suggestions for adjustments needed are based on an analysis of information gathered, and often special research or investigation into the problem initiated by the committee.

2. A second distinctive method of handling information cooperatively was found to be through a central department of a management and research group.

3. The third type found resembled the second. It was a pooling of information by competitors, excepting for the more highly organized manner in which it was conducted. In a few cases the central division of the management and research group had the authority to require that adjustments suggested be made by members. All three of these plans operate on the principles of centralizing this function of collecting and distributing information, and of increasing the range of activity and value of the service by cooperative efforts and specialization of the work.

The Central Information Department. The remaining method found of handling the problem was to centralize the function in some staff department of the company's organization, such as the research or statistical department, but more commonly in the company library or a central information department which usually had jurisdiction over the company library. This department then acted as a clearing house for all information both from internal and external sources and maintained files of all information on changing conditions. The usual organization of such a department is to have it in connection with the company library and information files. It may or may not also be the research department. In any case it works in close cooperation with the research, statistical, and other similar staff departments. All trade journals in the field are subscribed to and go first to this department, as does all other

information on changing conditions, whether from trade associations and other outside staff groups or from the various internal sources of information. A suggestion system is maintained which solicits ideas and information from executives. The information once centralized is classified and routed to the points of utilization within the organization. Executives are requested to furnish the information department with a list of subjects upon which they desire to keep posted. The department also endeavors to anticipate subjects upon which executives and committees will need information and provides it for them. In some cases notices are sent to executives informing them of receipt of information in which they may be interested. In other cases clippings, briefs, bulletins, or even the telephone may be used to notify them. One practice in dealing with articles in periodicals is to send the entire magazine to the executive, who then reads and returns it. Later all articles are clipped and filed serially and cross-reference index cards made out. One of the large oil companies maintains a file of over twenty thousand different articles, cross-indexed by subject and source. Often as many as twenty different reference cards are required to make information readily available. When information requiring analysis is obtained it is usually referred to the statistical department first, analyzed, and returned to the central information department, from which it is routed to executives as previously described.

Summary of Essentials for a Fact-founded Operating Organization. In formulating plans to provide for a smooth flow of prompt and reliable information on changing conditions there are many things to be considered. If the trade association in the field provides such a service in the form of a special committee for this purpose, it should certainly be used, although not to the exclusion of proper provisions being made within the company's own organization. This also applies in case the company is a member of some cooperative management and research group which furnishes this service. In some cases it may be desirable to establish a separate staff division handling this function exclusively for one department, such as a style bureau under the direction of a competent stylist. For style information cooperative action, such as through the trade association, is also essential. In general, however, it seems desirable to centralize the responsibility in the hands of a competent individual or group, a staff department organized for this purpose. This should be in connection with the company library and work in close cooperation with the research and statistical departments. All information relating to changing conditions should go first to this central information department and then be routed to executives or committees who are to use it. If necessary, it should first be referred to the statistical department for analysis and interpretation. That of value should eventually be filed in the central information file and be available at any time to all executives. In some cases it may be desirable to classify data according to whether it represents normal growth or rapidly changing conditions. Priority should always be given to information on changes which may necessitate prompt action on the part of executives. Assurance that information is properly utilized should be obtained by requiring that those receiving it report back stating receipt of information and what action was taken on it. If suggested adjustments are

also offered a similar procedure should be followed, coupled with the requirement for an explanation of reasons why, in case the suggestion is not acted upon. Contact should be made with all available sources of information needed. Full utilization should be made of the company's own facilities for supplying information on changing conditions. The public relations department can report on changing public opinion; the sales division and field men on changing conditions in competition, customer demand, new developments, etc., and the statistical and control divisions on analysis of the company's records. Every effort should be made to train executives to be alert for changing conditions and to cooperate by reporting their knowledge of developments. It will often be found desirable or even necessary to have scouts or field men studying changing conditions at first hand. Consumer surveys and other research should be conducted whenever it seems desirable. With proper provisions established for utilizing facilities within the organization attention should be directed to external sources, and contacts set up with every available source for the information required. Naturally trade journals and trade association publications should form the backbone of the system of external contacts. These groups are specialists in this work. Utilization of the remaining outside staff groups will depend largely upon the needs in each particular case. Obviously, in a small business it is not necessary to have an entire department devote its attention exclusively to furnishing information. However, even here, a definite placement of responsibility for this function should be made, preferably assigning the duty to the manager's assistant.

Forecasting and Anticipating Rapidly Changing Conditions

This is the second major division of management technique required to meet rapidly changing conditions. It is often of vital importance. While it may not always be possible to foretell accurately what changes are going to take place, it is often possible to anticipate them to some extent and be prepared for the emergency by having alternate plans developed and held in reserve should certain likely changes take place. Then, the mere fact of attempting to forecast or anticipate changing conditions tends to develop a forward-looking attitude among executives making them more alert in watching for changes and better prepared to respond quickly to the new conditions.

The Flexible Budget. The forecasting of measurable factors of a business, the operating results, by means of budgets or operating schedules is an accepted practice of good management today. In the preparation of the program for budgetary control conditions that will affect its operation are estimated as carefully as possible and taken into account in formulating the program. Once the program is formulated, it is still necessary to keep a close record of its value as a guide for the business to follow. Conditions affecting it may, and frequently do, change from what it was estimated they would be. Consequently, it is necessary at times to adjust the budget to take account of changes, and the idea of the flexible budget has been developed to facilitate this adjustment. The flexible budget is analogous to the alternate plans that can be developed and held in reserve by management to be

better prepared to meet changing conditions in other departments of business activity, changes that are likely to take place but not at all certain.

Business Forecasting. Somewhat the same technique that is applied to budgetary control of operations can be, and is being, applied to forecasting and anticipating changing conditions in general. It involves a careful analysis of causes determining existing conditions; forecasting trends in the changing factors; carefully watching the course of underlying conditions that determine the trend to anticipate the effects of any probable changes; and finally, the development of alternate plans to meet changing conditions likely to take place. It is based squarely on the study and prediction of trends, and consequently we see the great interest that is displayed today in the subject of trends. Books and articles are flooding the market on trends in this, that, or something else. We can read on trends in retailing, trends in consumer buying motives, trends in color, style, art, or whatever we wish. This trend study is occupying an important place in present-day management. It is probably the newest, as well as one of the most potent, tools in the kit of management technique for meeting rapidly changing conditions. It is certainly worthy of closer examination. In trend studies we are interested not only in knowing that a trend is in a certain direction, but also we seek to discover the forces that influence or cause the trend to be in a particular direction, in order that these forces may be used as barometers to give warnings of coming changes.

Analysis of Trends. A trend is a general course or direction. But toward what? What is the objective or goal toward which the trend is directed? Once we know that we have valuable knowledge to use in predicting the future course of events. It will usually be found that a general goal or objective exists toward which trends in a certain group of activities are directed. The path toward that general goal, however, is ordinarily not a simple straight line of progress but may wander around a bit, branch off into two or more separate courses, and yet all continue in the general direction of the principal goal. That is, any major trend is likely to be made up of numerous minor trends, all headed eventually toward the same objective but frequently taking divergent courses in the process. This is caused by the complexity of conditions or forces entering into the determination of any trend or trends. Also, one or more powerful influences may run counter to the general goal of the trend and succeed in temporarily retarding its progress in this direction, or deflect it into new channels. For example, a trend toward more completely satisfying consumer demand for variety in a given line by a multiplication of products may be carried too far and be subject to pressure from the simplification movement. This may check the rapid multiplication of needless variety yet not destroy the trend toward this general objective. Other factors may enter in, such as demand for variety in color, design, and price, which will set up several trends all directed toward greater variety but along slightly different lines. Another example might be cited in the case of trends in types of retail organization. The general goal or objective is economical mass distribution to accompany mass production. The major trend has been toward the so-called "chain store" type of organization. Yet other factors, in addition to the desire for economical mass

distribution, have influenced the trend, and we see it deflected toward a modified form of chain store type of organization; and also other trends in types of organization such as the so-called "voluntary chain" have arisen. Yet, these trends have the same general objective, although influenced by somewhat different conditions and taking divergent paths in seeking this objective.

Numerous additional illustrations could be given, but probably enough has already been said to illustrate the points that it is desired to emphasize, namely, that a study of trends in any field will usually show some major goal or objective toward which they are all more or less directly pointed, and that many other factors or conditions influence the trend and may temporarily divert its course or cause it to break up into several separate trends, and yet not destroy the principal goal or objective. This shows how important it is in trend studies to determine two things: first, the *general goal or objective of the trends*; and second, the *major conditions or factors influencing the trends under consideration*. When we know these two things about a trend we are in a position to deal fairly intelligently with the problem of anticipating and forecasting rapidly changing conditions in the field being considered. It will facilitate a more rational interpretation of trends, and lessen the danger of confusing disturbances produced by the other influencing factors with fundamental changes in the trend. Take the problem of rapidly changing consumer demand for style goods. If we know that the general goal of trends in this field is toward commodities that will more completely suit the needs of the user, and is not merely change for the sake of change, we have knowledge that will enable us to avoid many mistakes and to anticipate more accurately the course of future changes. Changing needs of the consumer can be studied and will act as a barometer of changes soon to be expected in style trends. The work of the modern stylist illustrates this point. This also shows the value of making consumer surveys in attempting to anticipate changing consumer demand. Often research through consumer surveys will show, on the basis of facts and not opinions, trends in demand or buying habits of which the consumers themselves are only vaguely, if at all, conscious. If, in addition, we know certain of the major conditions that will influence these trends, such as, for example, the limits within which changes are desired, —that they must be in the direction of the present renaissance in modern art, and work within certain limits of color and line effects—we have fairly definite guides to follow. Then we may also know that certain other factors will have a pronounced and immediate effect on consumer demand, such as lectures by noted authorities, activities of consumer educative agencies, advertising, news items, and particularly, in certain fields, announcements of discoveries such as that of vitamins. Each of these factors can be studied to determine the probable effect changes in it will have on the trend. Then observation of the progress of these influencing factors will act as barometers of changes which may soon be expected in the trend. In fact, whenever it is possible to determine the conditions bringing about or influencing demand in a particular field changes in demand can be forecast by following the developments of these influencing factors. Thus, building permits and construction work act as barometers for demands for electrical goods; peoples' habits of

living, for demands in consumers' goods, such as the recent change to lighter kitchens and resulting demand for light-colored kitchenware, or widespread interest in sports and resulting change in type of clothing demanded; or technical developments may act as barometers for demands for industrial equipment.

The forecasting and anticipation of changing conditions in the other factors may be conducted in the same way. If we know that equipment changes follow the general trend toward mechanization in industry, having as a goal or objective lower production costs and greater control over productive processes, we have gained one point in handling the situation. If it can also be determined that certain other factors influence the trend, such as the attitude of labor, desire for simplicity or beauty in design, new discoveries of the physical sciences, or of the science of management, we have additional barometers to use in predicting changing conditions in equipment. A similar analysis should be carried out for the other changing factors to locate important barometers to use in forecasting changes. In line with this type of approach, every effort should be made to forecast changing conditions of importance, making full use of trend analysis in the process. Careful record should be kept of the progress of, or changes in, the influencing factors and their probable effects taken into account in the forecast. As it becomes more and more certain that a predicted change is likely to take place, plans can be developed and held ready for use at the proper time.

Maintaining a Sensitive and Flexible Organization Readily Amenable to Change

Organization for Deciding on Adjustments. The third and final major division of the technique of management required to meet rapidly changing conditions is to maintain a sensitive and flexible organization readily amenable to change. To do this it is necessary to keep the entire organization in a healthy condition, have alert and well-informed executives with the proper attitude toward changing conditions, and establish definite authority and responsibility both for making such adjustments in the organization as may be necessary, and for providing a flow of prompt and reliable information concerning changes. Our survey showed at least four methods of placing authority and responsibility for making adjustments in the organization. In some companies, especially the smaller ones, only the *chief executive* has this authority. In a few cases adjustments were made only on orders from a *central committee on adjustments*, or similar body, which might be made up of the company's executives or be a committee of a management and research group to which the company belonged. In many cases adjustments in the organization were made only after *conferences of the various executives concerned*. The most common method, however, was to have authority for making all needed adjustments *centered in the line executives at the various levels of organization authority concerned*. That is, adjustments affecting only one department would be made by the line executive in charge of that department. If it affected more than one department it would be decided upon by

the next higher executive coordinating the departments involved, and usually only after conference with the heads of all departments affected. Adjustments of major importance, affecting the entire organization, often require authority from the board of directors or executive committee, but may be made in emergencies by the chief executive. In practically all of these cases it was customary for *the department charged with the responsibility of providing information on changing conditions also to suggest or advise what adjustments should be made.*

Maintaining Flexibility for Making Adjustments. In addition to toning up the sensitivity of the organization to respond to changing conditions as just described, it is necessary to insure a proper degree of flexibility, or ability to make the needed adjustments. Three factors in particular deserve attention: the physical factors, personnel, and organization structure. The rate of obsolescence in machinery has reached a point in some cases where management will not introduce a new machine unless it will pay for itself in from one to two years. In other cases changes have taken place so fast that it has been found desirable to use more general purpose machines in place of the single purpose ones formerly used, even at some sacrifice of operating efficiency. These two illustrations show the need for flexibility in machinery: keeping the *investment in machines in a more fluid state*, more capable of being changed in purpose to suit new conditions. Similar observations hold true for the other physical factors of plant and equipment. In another group of physical factors the need for flexibility is even more pronounced, namely, with reference to *investments in materials and merchandise*. This is apparent in many ways: the hand-to-mouth, or small-order, buying policies; closer inventory control; speeding up the process of manufacture and distribution so that investments in materials or merchandise will remain in a state not subject to change for the minimum amount of time. Of course other factors, such as economy of investment, also play a part, but the real pressure is to keep investments in as flexible a condition as possible, and be ready to meet rapidly changing conditions whenever they arise. *Flexibility in the factor of personnel* may be obtained by diversifying the training and experience of employees making it easier to shift entire groups from one class of work to another without loss of time or operating efficiency. In some lines especially subject to sudden changes in the demands made on different departments the flying squadron idea can be used. *The third factor to be kept flexible is the organization structure.* Several plans have been developed to meet this need, and many differences of opinion exist on the subject. Probably in certain cases the small department idea, permitting of rapid expansion or contraction of any division by merely multiplying the number of similar departments, using assistant department heads as managers of the new departments, will be as effective as any. There is much to be said in favor of a properly functionalized organization in securing flexibility of structure by the shifting of functions, or units of organization activity, to different executives according to changing demands made upon the organization. This refers to organization for operations on a functional basis, not to functional control, which is more likely to be highly inelastic. All of these methods of obtaining flexibility will be greatly enhanced in value if an adequate system of anticipating and

forecasting changing conditions provides management with some advance notice as to what it may be necessary to anticipate.

Methods of Deciding What Adjustments to Make. With regard to the methods used in deciding what adjustments should be made in an organization, there are at least three that were found sufficiently often in use to deserve mentioning. They are:

1. Study of the methods of successful competitors, particularly of the leaders in the field, will often show that they have already taken steps to develop a solution to the problem. Many times their experience can be profitably adapted to use by another concern with the necessary modifications.

2. Experimentation, based on adequate research, and carefully checked by watching the results on a limited scale at first will often prove to be an effective way of meeting new conditions.

3. Many problems are of such a nature as to permit a pretesting of proposed solutions in the research laboratory before attempting to put them into operation in practice. Numerous instances could be cited where companies have anticipated and forestalled difficulties by this method that were not apparent upon first consideration of the solution.

Summary. The technique of management required to meet rapidly changing conditions may be briefly stated as follows:

The organization must be operated on a basis of facts, by keeping all factors that determine the type of action it will take in tune with changing conditions.

Definite responsibility should be placed, and a systematic procedure adopted, for supplying a regular flow of prompt and reliable information to executives and committees charged with its use, making full use of both internal and external sources in securing this information.

Every attempt should be made to forecast and anticipate changing conditions by means of trend studies and similar aids, and a close watch maintained on conditions likely to produce changes of importance to the company.

Executives should be trained to keep alert for changing conditions.

And finally, the organization should be kept in a healthy state, sensitive to change, and flexible enough in all parts—physical factors, men, and structure—so that it may be readily adjusted to new conditions as they arise. There is plenty of information available today on changing conditions, and a knowledge of the technique of using it is developing continuously. Management can best meet rapidly changing conditions by operating on a basis of facts, using such technique as has already been developed, while striving constantly to improve it.

CHAPTER III

MANAGEMENT CONTROL

ELIMINATING IRREGULARITY OF OPERATION¹

BY HERMAN FELDMAN, *Professor of Industrial Relations, Amos Tuck School of Administration and Finance, Dartmouth College*

Fifteen or twenty years ago, periods of seasonal slack and times of general business depression were looked upon almost universally as mysterious catastrophies against which little, if anything, could be done by individual manufacturers. During the past decade, and especially during the past few years, there has been a remarkable change in attitude. While business men realize more than ever the need for intelligent economic action in the matter by the government, the Federal Reserve System, and other outside forces, they are looking chiefly to their own brains and ingenuity to steady their operations; and it is to their credit that already many of them have achieved noteworthy results.

In presenting a summary of the methods used by a wide variety of plants which have been successful in this regard, the usual caution must be urged. No one has a panacea for this problem. To mention a policy is merely to make a suggestion taken from the experience of other concerns. In this, as in all business matters, judgment and careful adaptation to the particular conditions are essential. But it should be noted that only those policies mentioned that have been found practical and are quite generally in use among firms which have reduced the irregularity of production and employment.

Perfect the Sales Side of the Business First. In discussing management's means of regularizing employment first place should be given to the subject of distribution, as more important than the other aspects, production and labor management. Every other method of steadying work or of providing for workers when they are unemployed depends chiefly on the degree of control achieved over demand. When individual manufacturers, alone or in cooperation with others, have acquired some influence over the kinds of goods wanted, the time when they are ordered, the amount desired, and other elements involved, the foundations for marked improvement in the steadiness of industrial operations have been laid. The technique of production planning and of personnel management have already advanced to the point where exact scheduling is possible.

¹ This is a summary of the chapters relating to management methods in Dr. Feldman's book "The Regularisation of Employment," Harper & Brothers. This book was prepared under the auspices of a committee of the American Management Association.

The attack on irregularity of production and employment must, however, come from all three sides. While the most important flank is that connected with distribution, it will avail little if not followed up from the side of production technique and reenforced by those supplementary methods of personnel administration which take care of the working force in the way most suited to the changing business situation.

A. Distribution Policies That Promote Steady Operation. The realization that the sales end of a business may, under proper analysis and treatment, be subject to prediction and perhaps control, is of the utmost importance in the problem of providing security of employment. Henry S. Dennison, a manufacturer who has regularized operation, has stated: "I can say that the principal part of the work of smoothing out that curve of production has been a selling job." Most manufacturers do not seem to have realized this, or to have believed much control possible.

If the important aim of regularization becomes a basic consideration of distribution, some of the modes of action illustrated in the following list, and in use in progressive plants, will be found of aid; or executives will devise others better adapted to conditions.

1. *Market Analyses.* a. Careful analyses of past records and present conditions in order to arrive at accurate estimates of the probable demand for the ensuing year; then planning production and labor requirements on that basis.

b. Investigating the causes of seasonal peaks of demand.

c. Studying the possibilities of developing new uses for products made, so that purchase of products may be stimulated during times of customary slack demand.

d. Seeking out new markets at home and abroad having different seasons, so that these outlets may allow for more regular production; developing a long-time export policy with this end in view.

e. Attempting to forecast cyclical changes in business by detailed studies of intraorganization statistics and those of outside economic conditions.

f. Planning against business depressions by discovering new outlets for goods, by developing new items capable of stimulating demand, or by other expedients.

g. Diagnosing non-cyclical changes of long-time trend and adapting the business to the conditions.

2. *Diversifying the Output.* Adding side-lines, fillers and new products which may be manufactured at different times from the production periods of the main line, thus filling in the customary idle time of men, plant and equipment.

3. *Reducing Excessive Variations of the Same Product.* Simplifying the regular lines of products by eliminating unnecessary variations and changes. (When a firm is producing an excessive number of variations of a product, all having the same seasonal peak, manufacture is reduced to small lots. Production for stock becomes uneconomical and discontinuity of work more likely).

4. *Modifying the Extremes of Style Changes.* Finding practical means of reducing the style hazard—in the shoe industry, in clothing, and other

stylebound trades—thus making manufacture in advance of the period of peak demand possible; this may involve limiting oneself to stable lines, trying to get action by the trade as a whole and other possibilities. It is admitted that this is no simple matter, but here and there individual manufacturers have found their way.

5. *Getting the Consumer to Buy More Regularly.* Removing the obstacles which prevent the consumer from buying during times of normal slack demand; stimulating off-season demand by advertising, by price reductions and by intensified sales activity; enlisting the aid of consumers' organizations.

6. *Securing Orders from Dealers Well in Advance of Need.* Establishing relationships with local dealers leading to their placing orders well in advance of the season, so that production may be begun earlier in the factory; developing special retail outlets, such as chain stores, stock ownership in the firm by retailers, etc., to make distribution policies more acceptable.

7. *Developing Long-range Policies of Business Expansion.* Using a long-range plan of expansion as a basis for determining whether or not it is desirable for the firm to increase its plant, equipment, and personnel when a sudden rush of business occurs, so that extreme fluctuations may be avoided.

8. *Coordinating Sales, Production, and Other Factors through Scientific Sales Planning.* Combining the various sales policies and production requirements into a master sales plan, controlling all the operations of the business for that period of a year, and spreading out the work as equally over the months as the conditions allow; working out scientifically the means by which this master sales plan may be realized completely except for modifications forced by current developments.

B. Organizing Production within the Plant. 1. *Production Planning.* While there are factors in one trade which prevent as steady operation as is possible in others, a good deal of the difference is due to poor organization of production in the factory, more specifically in lack of scientific production scheduling.

The established technique of production scheduling and control has numerous business advantages. Among these are the opportunity to collate orders and therefore to reduce unit cost, and to shorten the time of production, because every element of operation is planned, thus allowing the firm to double or triple its stock turnover during the year and to make better use of the money involved. The following points in favor of production planning, however, seem to have a closer relation to the problem of providing steady work:

a. It enables the executives to have the best available knowledge as to how long ahead the orders on hand will last and how busy the various facilities will be. The firm can thus direct more effectively the efforts of the sales department and, by calling for more business in certain lines, adapt orders to continuous operation.

b. The better knowledge of work ahead makes it possible to know what delivery dates can be promised. Thus the firm may avoid the acceptance of orders that will lead to rush and overtime work.

c. Stock items will be more effectively scheduled. It becomes possible to plan their manufacture when such production will help most to fill up empty

spaces in the factory schedule. Planning also enables firms to avoid manufacturing too much for stock at one time and later having to shut down departments because of this excess.

d. The availability of a picture of the conditions of production months ahead enables the firm to know whether or not it will be advisable to try to get business at cost or at a loss in order to keep the factory busy; and, if so, when it shall get such business and how much of it will be needed. Miscellaneous activities, vacations, repairs, etc. may be postponed to times when an unavoidable slack is likely to occur.

e. A better knowledge of the labor force to be required is gained by such a projection of information and planning. If the future of the firm does not seem bright, the firm can stop hiring workers and effect reductions in the number on its payroll largely or entirely through normal labor turnover.

f. Knowledge of the future conditions of various parts of the factory allows for planning the systematic transfer of workers between departments, and thus for making use of a force of regular employees rather than discharging one group and employing another. Such changes need to be foreseen, because training for the new jobs may be necessary before such interdepartmental transfers can take place.

2. *Manufacturing for Stock.* Manufacturing for stock as a device for maintaining production may be thought of in two different ways. In the first place, there is the planned manufacture of regular stock items at those times when their production fits best into the production schedule. The second form, more commonly thought of by those interested particularly in the unemployment problem, is purposeful production in excess of anticipated requirements for the year, or without a sure market in sight, for the purpose of keeping the organization together until conditions change.

It is important to understand that manufacturing for stock does not require the completion of the whole article in advance. It is quite possible to manufacture only the component parts of a product, leaving the assembly work and finishing processes for the time when the completed article is wanted. Where component parts of a number of different articles are standardized, that allows for the most economical and the least risky form of advance manufacture. To protect itself against merchandise losses a firm should select for manufacturing for stock a product with low material content and high labor content, as wages do not fluctuate as violently as prices of raw material.

3. *Production Research to Eliminate the Weather Factor.* In some instances it is believed that manufacture can not be carried on at certain seasons because of the effect of the weather on the processes involved or on the personnel or on the product itself when it is perishable. But such handicaps need never be accepted as controlling. Brick making, once requiring drying by the sun and carried on only about half the year, was released from the control of the weather by the development of artificial drying. Outdoor construction operations have been held impossible in winter until some one has gone ahead and performed them.

Where the effect of warm weather rather than of the cold is the condition complained of, refrigeration may solve the problem. This was the solution

found by the packers of Dromedary dates. That product, which was peculiarly liable to deterioration, has been improved by chemical analysis and refrigeration, and that has made it possible to put date packing on an all-year basis.

4. *Utilization of the Dull Period.* When all efforts to spread out production have failed to supply the amount of work needed to keep the factory busy, and a slack period is foreseen, the postponement of many miscellaneous activities for the dullest part of the year may be the means of avoiding a lay-off.

Among the activities postponed to slack periods by alert firms are major repairs, special construction work, minor repairs, changes and improvements, and the scrubbing and painting of various pieces of apparatus and parts of the plant. The establishment of a common vacation time for everyone in the firm, corresponding to the slackest two weeks in the year, has been in favor among a number of industrial concerns.

5. *Budgeting the Hours of Work.* When, in spite of all the technique brought to bear upon the situation, seasonal fluctuations do persist, still another means of reducing the need for an outside labor force reserve is worth considering. That is the budgeting of hours of employment, so that an average number of weekly hours is worked during the year rather than a standard number throughout. If, for example, a plant desired to maintain a forty-four hour week, it would be no injury to the employees from a monetary standpoint to work forty-eight hours during some weeks and forty hours in others, on a pre-arranged basis. This plan makes for flexibility of labor forces without recourse to temporary hiring from the outside, and thus brings regularity of employment even though production requirements vary.

C. *Personnel Policies That Promote Steady Work.* 1. *Planning Personnel Requirements.* The conditions of industry are such that developed technique is needed to avoid unnecessary disturbances in employment. Changes in the number of persons required on various operations may occur as the result of numerous conditions, some customary or expected, and others sudden and unexpected, arising from variations in production from day to day.

As in the distribution and production aspects of business, the first emphasis must be on intelligent foresight and planning. Where a change in personnel requirements is in response to customary seasonal changes in the volume of work or to other conditions which may be foreseen, that should be provided against in advance.

Firms will therefore do well to seek out possibilities of making almost automatic interchanges between certain types of work. There may be some activity or department in a plant which is always slack at a certain time, while another activity or department may always be busy at that time. The warehouses and packing and shipping rooms of many firms allow for such automatic transfers, because when the work of manufacturing is complete or production has begun to slacken, workers are usually needed in the packing room, or the shipping room requires extra labor.

Obviously, a central agency must be available for clearances in labor requirements, with a knowledge of the present requirements of each department and of probable future needs. It must control the hiring of new employees and

the discharge of present ones. Progress cannot be made in balancing a firm's labor force in a plant where foremen hire and fire as they please.

2. *Training for Transfer.* The problem of training is intimately related to the possibilities of transfer. The impression is prevalent that without some expensive and formal system of instruction little interchange of work can be made. The best results will be obtained, of course, where training of workers has its honored place. But there is an opportunity, also, to balance work through less formal instruction.

In a number of factories where there is no training system as such, when a vacancy develops in one section while there is an overcrowding in another the workers are transferred even though they have not been previously trained. They may receive their instruction for the first time by working on the new process. The next time that kind of transfer is made each worker becomes more proficient in it and eventually is able readily to perform standard production on two jobs.

A Rounded-out Program Essential. In conclusion, the stabilizing of sales, the steadying of production, the regularization of employment, all are parts of the same problem. There is rarely any one policy or trick which will achieve the complete result. In most instances success depends on a rounded-out program in which every factor causing irregularity of operation is given its proper attention.

Concerns today which are not attempting to stabilize their business and are not planning ahead for steadiness of production and employment are, from the competitive standpoint, at a disadvantage. Any employer who has analyzed the cost of idle plant and equipment and the expense of hiring, training and developing workers who have to be laid off, or who has reflected about the intangible effects of insecurity upon the executives and the working force, is certain to be keenly interested in reducing, and if possible eliminating, these evils.

ESSENTIALS IN BUDGETING

BY FRANK L. SWEETSER, *Partner, Stevenson, Jordan & Harrison*

What Is a Budget? It is not what most people conceive it to be. It is not figures about sums of money to be set aside for definite expenditures, nor is it a series of graphic charts, nor multitudes of sheets indicating limits not to be exceeded. It is a psychological device. Its primary object is to make people think, to make everybody in the entire organization think. It is hard work to think. We all need something to help make us think.

Why Have a Budget? Every business needs a carefully planned, complete budget of all of its operations, because without it we guess, we jump at conclusions and find out too late that we were wrong. Knowledge is power; therefore, we get the facts.

We need budgets to serve as a basis for comparisons that are better than those in common use. It is unfortunately true that accountants for the most part always have insisted and still persist in making our statistical comparisons with past history, such as last month, the same month last year, or the

same period last year. By the use of a budget we secure a new point of view; instead of looking backward we propose to look forward. It is necessary, of course, to use the past and all the historical facts available, but these alone are not enough. We must add the best knowledge which the best brains in the organization can furnish to project into our budget standards of performance which will serve as a basis for comparison with current events in the coming months.

When properly prepared and used, the budget becomes the best kind of executive tool. It eliminates guessing. It makes accounting effective. It points the way to action. It enables the key men of the organization to reduce costs by the elimination of unnecessary waste and gives that assurance which is possible only through mastery of any situation.

FIG. 1.—Departments; indicating responsibilities and authorities in the organization.

Preparation. The first step in preparing the way is the *organization of the personnel*. Thus human relations come first. The entire business should be departmentized (Fig. 1) in such a manner that the responsibilities and authorities of the organization layout are recognized. It is usually desirable to prepare an organization chart (Fig. 2). In a manufacturing business there would be two classes of departments (1) operating departments or those

which produce the product and (2) the contributory departments which are those rendering service, although not actually engaged in the process of manufacture. Each of these departments must be headed up by an individual whose responsibilities are clearly defined and who accepts the authority for the proper conduct and cost of operation of the activities of his department.

It is essential to departmentize activities, using the most natural arrangement, either by locations, functions, or authorities. Always a department must be composed, not alone of groups of equipment or space, but also of persons, in charge of a definite, responsible head.

An example is given on page 1537.

The selecting and training of executives is of tremendous importance, although commonly done without thought about the future needs of the business. We have all noticed that when we get the right man or woman on a

Fig. 2.—Chart of Executive Organization and Functions.

particular job our difficulties cease, but when the wrong person is in charge trouble is ever present. If our budget is to perform its purpose, we must have the right leadership and personnel, both for its origination and its execution.

It is essential that each key man shall provide himself with an understudy for his own job. This feature is so important that it should never be overlooked. One of the interesting tests which can be applied to any executive in the organization is this: if the key man is a good leader and a good teacher and passes over to an understudy all he knows, he is good and ready for promotion. If he keeps his knowledge to himself and does not train an understudy, watch him; he will not grow.

Budget Committee. A budget committee has definite responsibility for coordination of all budgets and is responsible to the president or executive officer. If possible, the chairman of this committee should be a comptroller of the company or the officer who has three functions in hand. This committee should be composed of three members, one each from the production and distribution activities, in addition to the chairman.

Conference Groups. Without doubt the most effective method of preparing the personnel of the organization as well as the mechanism by use of which the benefits of budgetary control are to be secured is to organize various conference groups. *There are to be no secrets.* It is not only undesirable as well as futile, but really impossible, to manage a modern business set-up on a budget plan, using standards and incentive compensation methods, and at the same time stick to the obsolete idea of expecting department heads, key men or subordinate officers to be intelligent in their conduct of business without having the facts.

Moreover, progress in life, both social and industrial, is largely a matter of education. The wrong way to proceed is for the president, comptroller or some other officer to work up a budget, then impose it on the organization. The correct procedure is for the committee to organize groups. One such group would be charged with the preparation of the financial budget, handling the cash forecast, embracing current receipts and expenditures as well as projected capital requirements. Another would be responsible for the production budget, covering materials and supplies, direct labor, and manufacturing burden. The distribution budget conference group would develop market analysis, sales quotas for trading areas, product analysis, direct selling expenses, and selling administration expenses.

The budget committee of three handles the master budget and acts as a coordinating, guiding, and stimulating overriding agent responsible to the executive officer of the company. These various groups, therefore, eventually not only prepare the budgets with intelligence, but they also sell the plan to all others.

No successful budget installation has been accomplished without the full enthusiastic support of the management. Those which have been outstanding in their results have been guided by chief executives whose vision, open-mindedness, and ability to overcome obstacles have been outstanding.

Setting Standards. Perhaps the greatest change in accounting practice during recent years in industry has been the rapid growth and acceptance of the idea of standard costs. Formerly manufacturing enterprises were operated largely as one man concerns. This man through sheer ability was able to make shrewd guesses, which guided the organization during the fiscal year at the end of which, by means of a physical inventory and complete check-up, determined upon the progress and standing of his business. About forty years ago the idea of some kind of costs began to percolate through the minds of business men. Then followed for the next quarter of a century a gradual acceptance of cost accounting, based upon job costs. Under this method costs presumed to be actual were gathered covering all items of manufacturing. Some attention was paid to selling and administration costs, but as a rule these were rather sketchy.

Latterly, largely through the activities of such agencies as national associations, professional accountants and engineers, together with the cooperation of far-seeing executives, it has become the practice to adopt standards for various purposes. Out of this idea has come the acceptance of the principle of standard costs. Budgets and standards are not identical, but they are closely related. Since this discussion is concerned with budgets, it will

be sufficient to mention that standards for costs and for all activities are one of the essential foundation stones upon which the budget structure must be erected.

One of the most interesting and helpful contributions of standard cost accounting to budgeting is the development of the idea of idle capacity, by means of which only those costs are charged to the products which represent normal maximum operation while the extra costs of overexpansion and overextension are charged to management, as they should be.

Planning the Records. Organization, personnel, committees, and standards are not enough. Planned records for the administration of the budget must be prepared. These records as well as those of the accounting and cost departments must be definitely arranged to fit into the responsibilities and authorities. The record-keeping plan should always follow and coordinate with the organization chart. Simplicity is always better. There are many records too complicated. The first question to ask about any record is, can it be eliminated entirely?

It is usually possible, as well as economical, to have the records so planned that most of them can be used with equal facility by the departments of costs, accounting, budgets, and incentives, thus avoiding the building up of a record-keeping structure unnecessarily expensive in its operation. Nevertheless it must be possible to secure from the records those figures which are necessary to establish the budget requirements, the adjustments to meet conditions or to correct errors, and to indicate the performance. When finally and completely prepared, the budgets must cover all of the requirements of the various departments.

An example of a chart of accounts with voucher distribution and expense analysis is submitted in Fig. 3. The decimal classification ties in with the cost accounting, departmentalization, and general ledger control.

Forms. The forms to be used for the records are relatively unimportant. There is no standard type, size, or arrangement that can be announced as most satisfactory. This is for the reason that each individual concern has its own ideas and its own established procedures, all of which should be considered and molded into the picture. Some executives prefer one thing, while others are quite differently minded. It may be said in general that usually existing forms and records form a large percentage of what is required.

It is important, however, that the interpretation and presentation be such that the facts will be quickly observed. To accomplish this it is necessary to study the natural desires of those who are to use the information. Sometimes it is better to employ the narrative form precisely as if you were writing a letter. For those who like figures the amounts in dollars and cents or units of quantities or both will be most acceptable. Others will prefer ratios and index numbers, but for those who understand them graphic charts are undoubtedly most expressive. Everything in the world is relative; and whatever form of record or presentation is employed, it should be remembered that the purpose of the budget is to make people think. This thinking is to be about the coming period, and the relations are to be shown by comparisons with what ought to be and not with what has been.

CHART OF ACCOUNTS
(Decimal Classifications)

The function of the general ledger is control, while that of the voucher distribution is complete analysis. The arrangement shown with the use of decimal classification greatly simplifies the whole accounting and budget procedure.

Classification numbers are coded on all vouchers with vouchers covering all possible transactions in line with the following outline.

The first and second digits to left of all numbers govern general ledger accounts exclusively; following to the right digits three, four, and five represent further classes; then comes a decimal point indicating that the department number follows after the point, thus: 9311.93—93 to the left indicates general ledger account Expense No. 93, 11 indicates Executive Salaries, and .93 Design Department, covering (A) General Ledger Control, (B) Complete Analysis of Voucher Distribution, and (C) Departmental Expense Control.

GENERAL LEDGER ACCOUNTS

1 <i>Cash and Book Assets</i>	6 <i>Current Debts</i>
11 Cash in bank	61 Notes Payable
12 Petty Cash	62 Accounts Payable

FIG. 3.—Chart of accounts with voucher distribution and expense analy.

Standard Practice Instructions. An excellent by-product of the conference group method, not alone in budgeting, but in all other activities, is the development of detailed instructions. There is no better tool for the prevention of buck passing, alibis, or fall-downs than to have written instructions issued for all procedures. Such a basis of operation should not be entered into lightly. It is no sinecure to prepare standard practice instructions. Those who have attempted it will understand.

Incentives. A natural development arising from budgetary practice and standards is the use of incentives as a basis of compensation. Incentive compensation may be grouped under three classes:

1. Profit sharing for higher executives exclusively, usually the officers of the company.
2. Saving sharings for key men, such as department managers, foremen, etc.
3. Workers' bonuses based on intimate intensive time studies of the elements of the particular operation concerned.

Indirect workers of all kinds are tied into either the key men or the workers groups, so that every employee from the highest to the lowest feels the urge of extra compensation paid for extra effort.

Installation. No attempt should be made to install a budget procedure until the entire organization has been fired with enthusiasm for the idea through participating in its preparation by means of contacts with the conference groups and committees. It is useless to expect performance or cooperation until everyone understands. Operating heads as well as field men must be brought into the picture and made thoroughly conversant with the plan, in other words, sold on it before starting.

Year Basis. It is customary to use the operations of a fiscal year as the primary base with a breakdown corresponding to the character of the business by seasons, quarters, months or accounting periods. Seasonal trends should be recognized by a study of previous records so that the budget for January, for example, may be based on the probable proportion of that month to the year's business, and for the other months in the same manner. A product breakdown is desirable, especially in considering sales quotas and manufacturing capacities.

Adjustments. Bearing in mind that the standards and budgets are no part of the regular accounting but are merely measuring sticks, it should be realized that frequent adjustments, based on facts disclosed by operations or further study, are desirable. Changes in capacity, schedule, conditions, or whatever may be the basis of adjustment should be met when it becomes evident that such a change would be beneficial. In this connection emphasis should be placed upon the purpose already delineated. It is not expected that figures of budget and actual figures will precisely coincide. Indeed, such a coincidence might be the basis of the suspicion that all was not well. Budgets in industry are not appropriations of money to be kept until expended for definite objects, although this is true in municipal and governmental affairs.

It is expected, however, that the individual at the head of any department or activity will assist in originating the budget allowances, will agree to the

final budget as set up, will endeavor to carry out its provisions, and will not only be able but willing to explain the reasons why the budget did not balance insofar as his control is concerned, so that he may grow in ability to make adjustment to the present budget and to prepare more intelligently those for further periods.

Summary. Reviewing, in brief then, the most important considerations are the human relations. The greatest benefits of budgeting are its by-products. It is a definite urge on the executive officer and provides him and his associates with the knowledge required to permit him to focus his own super-power on those activities which most need it. Budgetary control makes people think and causes them to look forward instead of backward.

Unorganized guessing is eliminated. Opportunity for the selection and advancement of individuals is provided. Activities are coordinated. Departmental fences are broken down by the interchange of ideas and thoughts in organized conferences. Standards which are essential for modern cost accounting and for the measurement of performance find their natural outlet with greatest use.

Planned records, simplification of procedures, definite instructions, and incentive compensations increase profits and reduce costs.

Many say: "It can't be done." But it has been done. It is continually being done. It will continue to be done. Only those who have vision, energy, and stamina can do it. Anyone of that class, will have no difficulty. How can the top executive, who after all is only human, be expected to guide the ship unless he has the cooperation of his organization in such matters, and who is better fitted to forecast the future possibilities than those who daily observe the facts, figures, and events going on under their authority?

The results which may be expected are: comparisons based on the budget instead of history, better knowledge of what happened and why it happened, guidance for the stabilization and increase of future profits, and that training of the organization which inspires confidence while creating enthusiasm and initiative.

THE BUSINESS SURVEY

BY HAROLD VINTON COES, *Manager Industrial Department, Ford, Bacon & Davis, Inc.*

Definition. A business survey or report is a comprehensive examination of a business as a whole with reference to its capital structure, management policies and practices, organization, personnel, administration, markets, competition, merchandising, transportation, products, inventories, processes, production costs, and working capital, to determine the present position of the business, and to make a comparison of the results of operation with known standards; to reveal existing defects and trends towards unsound practices; the means for their correction and the coordination of functions and activities. These surveys, sometimes called *industrial audits*, when they are periodically made, permit a reasonably correct picture of the business, as a going concern, to be drawn.

The business survey should not be confused with audits or valuations. An audit is an arithmetical presentation of past transactions or facts interpreted by figures.

A valuation or appraisal is an engineering cost determination of the fixed assets as of some predetermined date for some predetermined purpose.

Business Phenomena. The following phenomena in business are familiar:

Certain industrial units grow and expand; others drift or decline; whole industries and businesses pass from the control of one set of owners to another; certain parts of the country enjoy good business with development and expansion; other sections are at a stand still; others experience recession; supposedly financially sound and apparently healthy businesses, many whose names are a household word, which have been synonymous with power and prestige suddenly, and without warning to the public, are in trouble and before one is aware that a change is or has been taking place, their position in the industry has been supplanted by others who had scarcely been considered as even encroaching on the business of the former.

It is the province of the business survey to ascertain the underlying reasons for these every day occurrences.

Success Factors in Industry. The success and prosperity of any industry generally depends upon the following factors:

1. The economic need for the article or articles.
2. The organization, personnel and management policies.
3. The type, character, condition, relationship, and arrangement of the production facilities.
4. The departmental layouts and condition of the fixed plant and its service facilities.
5. The plant or business location and the balance of its economic factors.
6. The adequacy and effectiveness of the research, merchandising and distribution organization.
7. The financial structure and the policy pursued.

Unfortunately, the ordinary financial statement generally presented does not and cannot go far enough behind the scenes to give a correct picture. The statement usually tells what has taken place; what one really needs to know is what is likely to or about to take place; two totally different and distinct things. The financial statements will not give any information, as a rule, regarding the seven points previously mentioned, except possibly the last—the financial policy pursued—and probably it will not reveal all the important and underlying facts on that.

We might go a step further and say that the success of a business today rests upon a knowledge of the political, sociological, psychological, economic and technical laws pervading most businesses. A business survey made by those properly qualified by training and experience can supplement the statements in such a way that the two will give a reasonably correct picture of intricate situations and it can be made to indicate the favorable and unfavorable trends.

Classification of Business Ailments. The survey should disclose the principal reasons why a company is not making adequate returns on its invested capital. Poor or inadequate earning power is usually traceable to

the violation of known economic laws and fundamental business principles. In general, the major difficulties will usually be found under one or more of the following classifications:

1. Incompetence in general management.
2. Inadequate working capital (or frozen working capital).
3. Manufacturing cost of goods sold too close to the prevailing selling prices.
4. Expensive, inadequate and obsolete manufacturing methods.
5. Expensive, inadequate and obsolete selling and distribution methods.
6. Poor and expensive financial structure and involved corporate structure.
7. Poor organization set-up and organization policies.
8. Obsolete plant equipment.
9. Uneconomic plant location.
10. Bad purchasing and purchasing policies.
11. Unsound labor conditions and policies.
12. Lack of adequate coordinated means for control of all phases of the business.

The survey should disclose not only the general nature of the ailments and defects in the business, but it should serve as a basis for determining what remedial measures should be applied and where.

The more thorough and accurate the survey the more reliable the conclusions and recommendations and the more readily the installation of the remedial measures can be made.

Probably the most valuable feature of a business survey is its impartial exposure of the principal factors affecting the profit and loss statement. Frequently the real significance and importance of these factors is not realized, the operating records and statements do not reveal them in sharp enough contrast for the management to perceive their real importance or their trends. Often it attributes the difficulties to factors or conditions that are primarily not responsible, or if responsible not to the degree imposed. The business survey on the other hand places before the management the significant facts, their correct relationship and import in such a manner that it is possible to isolate the problems and set about their solution in accordance with their relative importance in producing profits or reducing losses.

Such a survey places the management in a position to be able to present to the board of directors the real facts of the situation as contrasted with opinions that members of the board may hold by reason of their long association with the business, but necessarily superficial knowledge of its significant details. It is frequently difficult for a management to overcome these opinions and to modify existing policies and methods that it is believed are adversely affecting the business without a survey presenting the real facts of the situation.

A typical survey of production and sales would deal with the following subjects:

Production:

1. Analysis of production methods.
2. Design of product for economical manufacture.
3. Standardization.

4. Planning.
5. Preparation.
6. Scheduling.
7. Dispatching.
8. Raw and processed inventory control.
9. Labor control.
10. Equipment control.
11. Adequacy of equipment and processes.
12. Material handling.
13. Plant and departmental layouts.
14. Sequence of operations.
15. Organization.
16. Effectiveness of means for planning and control of production.
17. Manufacturing expense per unit of product.
18. Relationship of manufacturing costs to selling prices.

Distribution and Sales:

1. Analysis of markets.
2. Sales planning.
3. Sales execution.
4. Means, methods and machinery of distribution.
5. Sales personnel and organization policies.
6. Methods and procedure, results analysis.
7. Pricing policy, advertising, and publicity.
8. Sales forecasts.
9. Coordination of sales and production.
10. Selling expense per unit of sale.
11. Relationship between cost of sales and selling price to consumer, discounts, etc.
12. Derivation of gross and net profits, by lines, by territories, by salesmen.

Typical Studies. Typical studies that may be made for a business are:

Plant Layout. Studies to determine present and future requirements, location and arrangement of departments, equipment, service facilities, proper flow of work, sequence of operations, and economic utilization of space.

Plant Location. Investigation and studies of focus of economic forces determining the adequacy of the present location or the proper one for a given industry.

Rehabilitation of Existing Plants. Studies to determine plan for physical reorganization and rehabilitation, modernization and improvement of existing plant, providing the location is economically sound.

Power and Service Facilities. Analysis of power generation and transmission costs; air, gas, water, and electrical energy, material handling, yard and internal transportation.

Cost and Costing Procedure:

1. Direct and indirect costs.
2. Cost of raw materials.
3. Labor.
4. Manufacturing overhead.
5. Distribution overhead.
6. Administration and non-departmental expenses.
7. Methods employed and results obtained.

8. Uses made of figures and statements.
9. How do they facilitate control.
10. Means for comparison, control, and reduction of costs and expenses, tie-in with the general books.
11. Reflection in balance sheet and profit and loss statement.

Budgetary Control. Mobilization of past experience, statistical data, present factors and policies, and future condition for the establishment of budgetary control, coordination of sales and production, establishment of sales and production quotas, comparison and control of all detail budgets by a master budget. Reports and the means to provide executives with necessary classified and coordinated information to permit intelligent operation and regulation.

Office Methods and Accounting. Analysis of operating systems and procedure with a view of simplification, elimination of waste, reduction in time, introduction of mechanical devices, standardization and improved operating, accounting, and cost control.

Office Layout and Equipment. Survey of office space and planning to meet present and future requirements of the work with layout so that the flow of work will be expedited and the space utilized to the best advantage.

Executive Compensation. Method of compensation of executives, length of service pensions, retirements, character of the systems and the results obtained.

Personnel. Consideration of sound policies and practices in the selection, training, promotion, welfare and remuneration of employees, including the incentives, records, rating, and training courses, etc. used.

The Comprehensive Survey. A comprehensive business survey, depending in its detail upon the type of business, would ordinarily secure essential data somewhat along the following lines:

I. Plant and equipment.

A. Buildings.

1. General description, history and location.
2. Type, condition and adequacy.
3. Accrued depreciation, maintenance and obsolescence.
4. Fire protection.
5. Value of (optional).
 - a. Present day.
 - b. Insurable.
 - c. Going concern.
 - d. Liquidated and salvage.
6. Physical, geographical, economic and legal limitations.
7. General arrangements, departmentalization.

B. Equipment.

1. Type, condition, and adequacy.
2. Accrued depreciation, deferred maintenance and obsolescence.
3. Value of (optional).
 - a. Present day.
 - b. Insurable.
 - c. Going concern.
 - d. Liquidated and salvage.
4. Present utility.
5. Efficiency.
6. Capacities.

- 7. Machine balance.
- 8. Bottlenecks.
- C. Transportation facilities.
- II. Raw materials.
 - A. Where and how furnished and accessibility to
 - 1. Finished goods.
 - 2. Semifinished goods.
 - B. Cost of.
 - C. Cost of handling and transportation.
 - D. Methods of receiving, checking and distributing.
 - E. Condition of and methods of storing.
 - F. Quantities normally carried.
 - G. Method of pricing.
 - H. Purchasing methods, policy, contracts, scheduling.
- III. Labor.
 - A. Class, type, number and sex of employes and labor policies.
 - B. Turnover and reasons.
 - C. Employment methods.
 - D. Wage payment methods.
 - 1. Bonus.
 - 2. Premium.
 - 3. Stock sharing.
 - 4. Profit sharing.
 - 5. Other methods.
 - E. Welfare work, plant community policies, facilities, educational policies and work.
 - F. Industrial relations.
 - 1. Safety committees.
 - 2. Shop committees.
 - 3. Shop representation.
 - 4. Industrial councils.
 - 5. Other methods.
 - G. Federal, state, municipal and union regulations.
- IV. Departments.
 - A. Layout.
 - B. Relationship to each other.
 - C. Sequence of operations.
 - D. Methods of handling work in process.
 - E. System of administration.
- V. Products.
 - A. Types of, units manufactured, range of lines.
 - B. Demand for, suitability as to public demands.
 - C. Competitive.
 - D. Seasonal demand for.
 - E. Specifications.
 - F. By-products, disposition of.
 - G. Patents, trademarks, etc.
 - H. Design, weaknesses, economy, etc.
 - I. Relative profitableness of various units or lines.
 - J. Standardization.
- VI. Handling materials.
 - A. Railroad and water transportation facilities.
 - B. Interurban and truck transportation facilities.
 - C. Yard, department and interdepartmental methods and facilities.

D. Routing and dispatching.

E. Coordination.

VII. Production.

A. Type of manufacture.

1. Continuous.

2. Intermittent.

3. Mixed.

4. Mass production.

5. Specialty production.

6. Jobbing methods of manufacture.

B. Costs.

1. Labor, direct.

2. Material, direct.

3. Indirect charges and shop overhead.

4. Cost per lot or per unit.

5. Comparative costs.

C. Factors limiting production.

D. Production economics.

1. Productive capacity of plants.

a. By departments in units and dollars; maximum, normal and average.

b. Plant operation on date of examination in terms of maximum productive capacity.

c. Excess capacity.

d. At what per cent of normal operating capacity can the plant break even? For each 5 per cent increase or decrease what is the corresponding gain or loss?

2. Operating ratio.

3. Ratio of indirect to direct labor.

4. Output.

a. Per employee in dollars and in units of product per year.

b. Per dollar of production pay roll.

c. Per employee (productive).

d. Per dollar of invested capital.

e. Per dollar of equipment.

5. Factory burden.

a. Methods of application.

b. Amount and distribution.

c. Methods of control.

E. Tools, jigs, fixtures, patterns, auxiliary equipment.

1. Adequacy, character, condition, degree of obsolescence.

VIII. Power.

A. Generated, purchased or both.

B. Methods of generation, distribution and use.

C. Cost per unit.

D. Shutdowns, maintenance, interruptions, continuity of service.

E. Power per unit of product.

F. Comparison of power plant economics with normal attainable.

G. Central station facilities and service.

IX. Cost control, collection and distribution systems.

A. Methods in force.

B. Accuracy.

C. Reflection of the facts.

D. To whom the reports go.

- E.* Are they made in sufficient detail, so presented and compared, and received at such a time as to permit intelligent and prompt action?
- F.* Do the cost figures tie in with the general books?
- G.* Are the books independently audited, how often and by whom, and when are the books closed?
- H.* Analysis of probable expense items.
- I.* Budgeting plan and procedure.
- X. Plant balance.
 - A.* As to departments.
 - B.* As to equipment.
 - C.* As to inventories.
 - D.* As to labor.
 - E.* As to orders and sales.
 - F.* As to invested capital, borrowed capital, and working capital
- XI. Merchandising.
 - A.* Distribution.
 - 1. Markets.
 - a.* Domestic, volume of.
 - b.* Foreign, volume of.
 - c.* What market surveys have been made?
 - 2. Methods of distribution.
 - 3. Price determinations.
 - 4. Terms of sale.
 - 5. Selling policies, territory restrictions.
 - 6. Advertising methods and policies.
 - 7. Competition, probable competitors.
 - 8. Permanence of market, actual, potential.
 - 9. Principal customers.
 - 10. Engineering analysis of sales.
 - a.* By territory.
 - b.* By classes of product.
 - c.* By cost per product.
 - d.* By classes of customers.
 - e.* Standardization.
 - 11. Policy with regard to
 - a.* New models, styles, changes in design, color, variety, etc.
 - b.* Replacements, repair parts.
 - c.* Complaints.
 - 12. Seasonal and territorial demands.
 - 13. Experimental and development policy.
 - 14. Research.
 - 15. Deliveries and shipping.
- B.* Economics.
 - 1. Ratio of total raw inventories to gross sales.
 - 2. Ratio of finished goods inventories to gross sales.
 - 3. Ratio of total inventory to gross sales.
 - 4. Ratio of plant investment per dollar of gross sales.
 - 5. Ratio of cost of sales to selling price.
 - 6. Ratio of selling and advertising expense to gross sales.
 - 7. Ratio of general administrative expenses to gross sales.
 - 8. Ratio of working capital to gross sales.
 - 9. Ratio of experimental and developmental expense to gross sales.

10. Ratio of annual gross sales to average current assets.
11. Ratio of net profits to net sales.
12. Ratio of net profits to invested capital.

XII. Organization.

A. Type of organization, chart of

1. Military.
2. Functional.
3. System of management in force.
4. Committee management.
5. Other forms.
6. Functions of personnel.
7. Duplication.
8. Overlapping authority.
9. Personnel, characteristics of, suitability.
10. Handling of routine.

B. Personnel.

1. Executives, assistants and foremen.
 - a. Type.
 - b. Duties.
 - c. Previous experience.
 - d. Ability.
 - e. Judgment.
 - f. General fitness.
2. Expert assistance.
 - a. Legal.
 - b. Accounting.
 - c. Merchandising and advertising.
 - d. Production.
 - e. Engineering.

XIII. Financial.

A. Banking.

1. Financial policy.
2. Bank lines.
3. Commercial paper.
4. Notes payable.
5. Notes receivable.
6. Contingent liabilities.
7. Credit experience.

B. Statements.

1. Balance sheets and operating statements.
 - a. Comparative.
 - b. Arrangement.
 - c. Comprehensive.
 - d. Adequate.
 - e. Audited.
2. Ratio of current assets to current liabilities.
3. Ratio of current liabilities to total liabilities.
4. Inventories, amount and how priced, reserves.
5. Receivables, condition, age, value, reserves, etc.

C. Securities.

1. Bonds outstanding, type, class, interest, etc.
2. Preferred stock outstanding, type, class, interest, etc.
3. Common stock outstanding, type, class, interest, etc.
4. Other forms.

5. Ratio of bond interest to net earnings.
6. Ratio of preferred stock dividends to net earnings.
7. Ratio of common stock dividends to net earnings.
8. Ratio of bonded indebtedness to plant investment.
9. Net worth.

D. Earnings.

1. Earnings statement, comparative.
2. Profit and loss statement, comparative.
3. Fixed charges, ratio to earnings.
4. Deferred charges.
5. Reserves.
 - a. Sinking funds.
 - b. Depreciation and replacement.
 - c. Bad debts.
 - d. Development and changes in the art to keep company abreast of the times.
 - e. Patents, etc.
 - f. Taxes.
 - g. Others.
6. Surplus.
 - a. Reconciliation of surplus account.

E. Working capital.

1. Ratio of working capital to total capital, and comparison with customary amount in industry.
2. Ratio of cash to gross sales.
3. Ratio of cash and cash resources to current liabilities.
4. Ratio of working capital to gross sales.
5. Ratio of current liabilities to gross sales.
6. Purchasing, methods, scheduling, turnover, terms of sale, diversion of earnings to fixed assets, etc., as affecting working capital.
7. Proportion of working capital frozen.

F. Budgets.

1. How prepared.
2. Set-up for comparison.
3. Arrangements for control.
4. Accuracy.

G. Methods of control.

1. Operations.
2. Scheduling.
3. Planning.
4. Material.
5. Labor.
6. Overhead.
7. Cost.
8. Reports.
 - a. Operating conditions.
 - b. Status of production.
 - c. Production costs.
 - d. Periods covered by reports.
 - e. Whom are they rendered to.

XIV. Purchasing.

A. Methods.

B. Source of supply.

- C. Purchasing statistics.
- D. System of follow-up.
- F. Control.
- XV. Engineering.
 - A. Force, type, etc.
 - B. Quality.
 - C. Efficiency.
 - D. Methods.
 - 1. Symbolization.
 - 2. Bills of material.
 - 3. Issuance and recall of drawings.
 - 4. Changes.
 - 5. Specifications.
 - E. Economical design.
 - F. Rejections.
 - G. Customers complaints.

It must be borne in mind that the survey must be so organized and so conducted as to cut clear across all the divisions of a business *without undue emphasis on the activities of one division* as compared with another unless in the course of the survey certain well defined weaknesses in a given division are revealed. Sound technique insures a correct perspective and this is the most important attribute of the business survey, since incorrect perspective due to prejudice or preconceived ideas will produce a picture inaccurate as to form concealing the more subtle dangerous underlying trends.

CHAPTER IV

USE OF RESEARCH AND SPECIALISTS

BUSINESS RESEARCH

By C. W. WILSON, *Manager, Research Department, Pittsburgh Railways Company*

Scientific Method of Dealing with Problems Available to All. Scientists and technical engineers long ago accepted the fact that they could not deal with problems in their entirety, but that they must work with isolated elements. Management is now rapidly becoming conscious that it, too, must follow this practice more extensively. It is frequently a vexing question to determine which elements of accumulated experience will continue to serve as structural material for policies and which must be discarded. The discovery and understanding of elements hitherto unknown, but which undoubtedly influence results, also cause much concern.

It is not only natural but inevitable, that the methods which have been profitably applied in experimental research for many years should be important factors in the application of research principles to management's especial use. The idea that scientific research is an instrument for the use of scientists and technical engineers only, and that highly trained specialists have a monopoly on research methods, has been recognized as the delusion it undoubtedly is. There has been a failure, generally, to distinguish between the accumulated knowledge possessed by those chiefly identified with scientific research, and the orderly method with which they solve their problems. Increasing numbers are also recognizing that there is a sound and relatively simple method or technique of investigation and problem solution; that while the details and the magnitude of problems may vary without limit, the fundamental types of their elements are essentially the same.

A Specialized and Detached Group Should Do the Work. Officials engaged in active management, though keenly alive to the situation, cannot prosecute research studies themselves. It is a physical impossibility. Someone, somewhere, free from the stresses of operating responsibility, must do it for them. Such work should be detached and as coldly scientific and impersonal as possible, though sufficiently close to actualities to prevent oversight of pertinent factors.

Theories Put into Practice. It was such views as the foregoing that led the company wherein the policies and methods herein discussed are in actual practice, to create a research department, Feb. 1, 1924. The company inaugurated its research policy in two ways:

First, by freeing individuals in technical and operating departments from operating pressure and isolating them so that they might pursue research work.

Second, by the creation of a major department, called the "research department," which is free from direct operating responsibility and devotes its research activities to management problems.

The department as now constituted is not the product of any detailed, preconceived ideas either as to organization or the nature and amount of work which should be done, but represents a gradual development in response to actual needs. The beginning was more like the departure of pioneers. The application of the principles of research to the problems of management is still generally in its early stages. The elements involved are intangible, and the spread of a common understanding as to effectiveness and value is necessarily slow. The fact that methods of profitable application cannot be developed at once, but must grow gradually, has retarded its broader use, though its value is generally accepted in principle. Then there is the opposition of those who sincerely misunderstand the scope of its possibilities. There is also the inevitable retarding influence of prejudice, for there are some who still believe in the continuance of practices which require scant application of research principles. The first attempts at anything are usually sprawling and frequently bristle with opportunities for improvement and refinement. The early application of scientific research to the use of management was no exception. In addition, pseudoscientists, who tried to exploit half-baked schemes to their own advantage, left a trail of obstacles which have to be overcome.

There should be an effort toward securing general acceptance that management research work has no mystery attached to it, but is simply an orderly application of sound method to solve every-day problems. The idea of mystery encourages the expectation of miracles, which invariably ends in disappointments.

It became increasingly apparent that if such a department were to develop, it must have a chance. A chance means proper official standing, adequate personnel organized as soundly as possible, and good working conditions. Creating a title and providing inadequate force does not make a research department capable of profitable production in quantity any more than a shop foreman and a helper or two can comprise an efficient machine shop.

The research department is a major department in charge of a research manager, who reports direct to the operating head of the company. The research manager is a member and chairman of a group of officials which functions as an advisory body in support of the operating head in policy matters. The work of the department as it functions at present falls roughly into three divisions, that performed by:

An economist.

An engineering division (which, in addition to a group of engineers, includes one section specializing in statistics, one in development of the property's recurrent work methods, and one in budget preparation and control), in charge of a research engineer.

A general office division (which performs general office service for all operating general officers but which has been made a division of the research department for reasons of economy and effectiveness).

The Problem of Securing Consumption or Full Use of Releases. The effectiveness of and justification for a research department depends upon the profitable consumption of its products. The mere production of studies, excellent though they may be as abstract research efforts, may not assure their profitable use or consumption. During the years of development of the department and its methods, the following elements have assumed outstanding importance:

a. Profitable consumption, or use, of its releases must be the main objective. An understanding of the consumers' needs must shape production effort from the time the project is set up until it is finished.

b. Priority selection is the heart of effective research production. Without adequate priority-selection facilities and the careful use of them, any department is bound to drift from its most profitable course.

c. A project placed in priority should be considered the equivalent of a product to be manufactured and consumed. The research department organization and personnel should be looked upon as the equivalent of tools and equipment needed for manufacture, and methods which produce the equivalent of line production applied to desk work should be used.

d. A careful treatment of presentation requirements is essential. Much otherwise able research work proves valueless to the consumer because the material is prepared from the viewpoint of the producer, and little effort is made to reach the experience and habit of thought of the consumer.

e. Follow-up machinery must be provided so that power is placed in the hands of the research department to see that no effort is wasted because some of its releases fail to receive proper consideration.

f. Before profitable consumption can be hoped for, a research department must demonstrate that it is not in destructive competition for credit with line departments.

Profitable Consumption. A manufacturer may sell his products by means of high-powered salesmanship, but if he fails to satisfy his consumers he cannot prosper for long. Research departments may likewise develop studies without limit, but if they are not put to profitable use the foundation of the department cannot be sound. If profitable consumption does not result, it should be the department's job to find out why. When a job is released, provision should be made for follow-up, and the record should not be closed until a brief, but comprehensive, statement is added to it showing the use made of the release and what it led to. This provides a sort of measure by which the department may check the effectiveness of its work in general and and that of individuals in particular.

Producing for the Consumer. A project placed in priority should be considered to be the equivalent of a product beginning to be manufactured. The objective in this instance is defined as the finished piece or work ready to be released; the purpose is what it is to be used for after it has been released. It is very easy to accept as a fixed handicap the limitations of an inadequate organization, and to assume that the consumer must and will adjust his

needs to the conditions in the department. Here management encounters the problem of expanding or contracting the research working force. Management need have no difficulty in reaching a decision, for the selective list referred to later shows clearly all jobs which have been set up and, consequently, what work is waiting to be done.

Priority. Timeliness is among the most important factors in achieving consumption, and a dependable set-up for sound priority control is essential. The department is visualized as a multiple instrument making a number of contacts, through each of which it bores into one of the group of problems most pressing at the time. The number of contacts is increased or decreased as the pressure for production increases or decreases. This flexibility in the structure of the department enables management to control research expenditure as conditions may warrant.

An unlimited number of jobs should be welcomed and each one should be identified by number, represented by something tangible, and placed in a selective list to await priority. The more jobs there are, the better chance there is that the one selected for production by the process of elimination will represent the most pressing economic need of the company at the moment. Urgency of need, comparative economic importance, and timeliness are the principal factors which control priority. Unless the absolute necessity of a sound priority procedure is generally understood, a research department will be helplessly chasing its tail trying to keep up with the most recent, but not necessarily the most important, requests or other forms of stimuli. Reason must rule if sound production is to be expected, and a reasonable executive will not object to being asked to make an "either-or" decision when the impossibility of doing two things at one time is presented to him in the proper way and he is given an opportunity to deal with something tangible.

Careful selection from a selective list of jobs for the preferred list is looked upon as one of the most important activities of the department. Ample time and discussion are devoted to this selection, for the preferred list is the equivalent of a chart, indicating the general direction in which the department is moving. This general trend of priority is established some time in advance of the actual production effort. There are emergencies, of course, and no plan works perfectly always.

Presentation Requirements. Inadequate presentation has prevented great numbers of excellent researches from achieving their purpose. The perfect presentation is fitted exactly to the needs of those who have to use it. The presenter of any group of facts or discussions, oral or written, assumes the responsibility of reaching the experience of those to whom such presentation is made. The expense of research releases is assumed by a company with the expectation that they will be useful. It is, therefore, the research man's job to develop the facts in an understandable manner.

Follow-up Machinery. If evidence that a research release has received consideration is not forthcoming within two weeks, inquiries are made. As a last resort, an official follow-up letter may go out from the research manager, with copy to the vice president. A release may be returned to the department by the consumer for any reason, provided some support for the reason is given; but the release must not be ignored after receipt. The department

is supported in the position that, as it must buttress its statements and findings by what it conceives to be fact, it cannot have them thrown aside by the mere unsupported opinion of some operating department head. He is expected to differ when he sees fit, but he must have some support for his opinion when he does so.

The Research Department Is Non-competitive. While the research department should strive to have its consumption record tell a constructive story, it cannot afford to forget that, as a department, it is maintained by the management as a tool for the use of all officers and employees. Its principal objective is to enable the personnel of the company individually to do better jobs. Tools that are used willingly and wholeheartedly do not compete with the user. If the department is so unfortunate as to create the impression that it is trying to grab credit at the expense of those whom it is supposed to support, it is creating an insurmountable barrier between itself and its proper goal of collaborative work. That is one of the reasons why the department has not compiled records purporting to show the specific economies and other achievements to which it has contributed. It could not, as a rule, have achieved any important advantage unaided by some operating department. It is believed to be a wiser policy, therefore, to watch carefully the consumption record and so learn the use made of releases. In this way, company officers are kept aware that the department is constantly contributing constructively to the economic welfare of the company, while at the same time they, who alone make the releases profitable by using them, are not antagonized by any boastful emphasis regarding specific achievements. The department must function in spirit and in fact as a service tool for the net good of the company as a whole, not as a department glorified by particular successes which other department heads may feel are achieved at their expense.

Type of Research Projects. Jobs originate literally from everywhere. They are set up in response to requests from executives or employees; or the department, in its work, discovers or identifies projects which require development. In fact, its jobs cover the entire field of management, from minute cost analyses to studies used in determining policies of major importance.

Coordination of Research Department Work with That Done in Other Departments. Specialization without coordination amounts to disorganization. Coordination between engineers and individuals in the department and those outside it is achieved by means of the identified job. Jobs are not assigned to individuals outside of the department, but the process of element identification makes coordination practical and easy. Jobs that require material or information from engineers in other departments are set up in the usual way and assigned to a research department engineer, who defines the request and who cooperates with whatever department is concerned. With a proper understanding that the research department is not competitive, and that it is a tool provided by the management in order that all line men may each profit more on account of better results which they are helped to achieve, the relation between research workers and line workers should be that of cooperators and costimulators.

Cost of Research. The pay-roll cost of the actual research work, as the name is usually defined, which is done by the research department, is approximately 0.16 per cent of the gross revenues of the companies served.

With the exception of a few nominal charges made to affiliated companies which function under separate corporate set-ups, the cost of the department is charged to overhead. The job system that is in use, together with the recurrent work authorities for all recurrent work, make it possible to charge with relative accuracy for each piece of work done, should it be desirable to do so. It is believed, however, that a greater use is made of the department as a tool for the benefit of the entire company if other departments are not discouraged by charges made to their operating accounts for service received. The research department is not, and cannot be, more interested in one operating department than in another. When its cost is considered as an overhead charge, the actual economic needs of the entire company have a better opportunity to influence priority determination. If charges were made to individual departments and had to be approved by them and their accounts had to reflect the cost, it would certainly tend to inhibit the free use of research facilities. This is particularly true if an operating department head is inclined to feel that his results are the best that can be secured, and that expenditures for research in connection therewith are relatively useless.

Should Research Departments Have Opinions? A research department should vigorously attack the practice of depending upon unsupported opinions. Its suggestions and discussions should set forth conclusions, but it should be clear that such conclusions are the result of a careful consideration of facts, which should be enumerated and discussed, if the requirements of clarity make such discussions necessary. Opinions, like definitions, are so apt to remain unchanged long after the structures which originally supported them have changed, that close watch should be kept for the beginning of their obsolescence. It is a common human tendency to feel that an opinion once expressed must be defended ever after, else a loss of prestige will result. It is much safer and wiser for a research department to assume the position that, as it interprets the facts as they are today, certain conclusions appear to be sound, but it is always possible for new conditions and new elements to appear at any moment which may render today's conclusions subject to modification.

Likewise, a research department, when endeavoring to secure consumption of its releases, should not accept a rejection or refusal to consider them based on unsupported opinion. It is obvious that if an operating department head could merely disagree and say that his experience indicates the suggestions made are impractical and that he does not care to take the time seriously to consider the alleged facts presented, a ridiculous situation would result. Often the most hallowed of practices may have served its purpose and should be subjected to a coldly impersonal analysis to determine the wisdom of its continued existence; and just as often the mere suggestion of such a thing is looked upon as little short of sacrilegious. It should be understood by all that the department is just as anxious to support the continuance of a practice, if the analyzed facts indicate it is still sound, as to point out weaknesses and suggest something new. The burden of reaching a common understand-

ing in such matters should rest upon the research department. The department should, however, be supported in a follow-up procedure that actually means something. Department heads should be encouraged to point out what they believe to be errors in statements or conclusions and should be helped to substantiate their disagreement if it is possible to do so. They cannot, however, be permitted to wave aside carefully developed research studies.

Research Personnel. The benefits to be derived from business research would be much more extensive if there were a more general recognition that the orderly effort known as scientific research is not a mysterious something performed by queer people behind closed laboratory doors and involving the use of extremely complicated methods; and further, that some excellent jobs of research are being done by quite ordinary people who do not dream they are doing research.

A keen observer who can recognize a fact, who can make intelligent distinctions between facts, who can be depended upon to draw sound inferences, who is a good judge of evidence when he is checking his inferences, and who has the patience and the concentrative power to keep after a problem until he has whipped it, is potentially a good research man. He, of course, must have the education and preparation that will give him the equipment of necessary knowledge to work in his particular field; but, if the inherent qualifications enumerated are not developed to a reasonably high degree, he will not make a good research man no matter how extensive his educational preparation may have been.

In the development of the research department referred to here, the engineering field has been turned to most frequently when new personnel has been needed. The department has, however, some men who are not engineers by training but who have done some excellent work and are considered valuable. They, however, it is believed, would have made good engineers if they had elected to enter that profession.

The Place of the Specialist in Management Research. It is obviously out of the question for a business research department of moderate equipment to include specialists in all lines in its personnel. It should, however, draw heavily upon the accumulated knowledge in the possession of those especially equipped and should have contacts which enable it to proceed quickly and without confusion in securing the services of men who have qualified as authorities in their respective fields whenever projects requiring highly specialized knowledge for their execution are placed in priority.

How Much Should a Company Spend for Business or Management Research, and How May Production Costs Be Controlled? It would greatly simplify matters if it could be stated that there is a way of measuring the result of such work exactly and to the cent. There are some few instances which are sufficiently isolated as to permit the exact measuring of results. Generally, however, such exact measure is not possible. The value and urgent necessity of a business research, on the other hand, can and should be amply obvious before it is begun.

As long as the business research effort is looked upon rather vaguely as a necessary but somewhat nebulous whole, the obvious value of the pieces of

work are obscured. As soon, however, as the true picture of a number of urgent individual projects takes form, the view clarifies. The need for solving the most urgent of these problems is so pressing and the fact that solution will result in value amply in excess of production cost is so apparent, that the idea of stopping to attempt to estimate exact benefits is impatiently pushed aside as a retarding and non-contributing detail. In most cases, successful releases are completely infiltrated into the work of operators. It is therefore evident that any statement regarding the allegedly exact value of a release must depend upon estimate alone. This would unquestionably result in conflicting opinions that could do little or no good and would frequently do much harm. The important thing is that the research release is profitably consumed either as a useful tool or necessary material in the hands of some operator.

It is helpful to realize that business research in reality is nothing new. It is simply the application of specialization and scientific method to something that has been attempted as a sort of side line by operators and executives ever since business began. The alert operator who visits other properties, attends conventions, writes stacks of correspondence in an effort to keep informed is trying to do for himself what can be done for him much more effectively through specialization.

Research is in the nature of organized pioneering, and pioneering cannot be reduced to an exact science. Many projects known to be indispensable do not provide means for the tracing of tangible values to them. Many aviators flew out over the various oceans and never returned; yet, in the judgment of those who are developing aviation, such effort and sacrifice is necessary. And the public does not question such judgment. Today, in all progressive enterprise, some pioneering must be done. The accumulation of all knowledge is slow and costly. The wonderful prosperity of the country today is due to the Bells, the Fords, the Wrights, the Langleys, the Edisons, and to those others who could visualize demands for things which did not, at one time, exist, and which must be perfected by means of much labor, much ridicule, much sprawling effort, and much refinement. The country today is being upborne by the spirit of applied research, so why should management deny itself the advantages which intelligent study of fundamentals and their application always brings, simply because in many cases the return, though amply obvious, cannot be measured exactly in dollars and cents?

The management of the company does not waste much effort in trying to build up estimates based upon opinions as to exactly stated values concerning what are known to be intangibles merged into the general activity. It is more concerned with the selection of the projects it is anxious to have developed into tools or materials known to be badly needed, and with the certainty that the methods used in such development insure complete consumption or use.

Research effort is the result of a state of mind. It is one of management's responses to the consciousness that changing conditions may render unsound a practice of long standing. Further, that this change is accelerated by modern development and modern demand to a rapidity of movement hitherto

unknown. Approached en masse and viewed as a sort of nebulous whole made up of half-identified units, the formation of sound judgment as to exactly what to spend for business research is difficult in the extreme, if not impossible. When, however, management identifies its problems, creates something tangible to represent each one, complies with the simple necessities of determining an intelligent priority, an easy method is provided for judging both the need and the value of research projects before they go into production. In this way management is provided with a flexible, an immediate, and positive control.

PRODUCTION CONTROL OF RESEARCH PROJECTS

By C. W. WILSON, *Manager, Research Department, Pittsburgh Railways Company*

"Production" Defined. By production is meant the completion in the form of a good job of whatever is undertaken, without destructive strain on the personnel, and without waste of time, or money. Obviously production is primarily dependent upon individual competency. So much has been and is being done by competent hands to improve individual capacity, however, that, for the purpose of the moment, a personnel with satisfactory qualifications is assumed. This study is directed at those forces which, regardless of the nature of the work, help or hinder desk workers who function as parts of a coordinated group, with the object of isolating, understanding, and complying with those elements which enable a management research department more nearly to avail itself of the benefits obtained by methods similar in principle to those used in line factory production.

Sound Production Dependent upon Compliance with Fundamental Forces. The achievement of production, as previously defined, *should* be the ideal, and *is* the responsibility of any executive assuming charge. The forces which influence production are inexorable, and everyone charged with the responsibility of transforming a pay roll into production should understand that unless the helpful ones are used and the destructive ones avoided, consciously or otherwise, pay-roll waste is bound to exist.

A Pertinent Question. A pertinent question appears at this point: If non-routine work of employees whose production is the application to paper of the result of mental activity is responsive to the forces which affect production in material things, why has industry not whipped it into line on a broad scale sooner, and made it conform to the equivalent of factory practice?

The reasons are many, but it will suffice to mention three which are among the most prominent:

1. Industry has been and still is inclined to look upon work charged to non-producing overhead as essential and indispensable, but hardly worth the engineering effort necessary to provide means to conform to the few essentials required to make relatively sound production possible.

2. Managements have been disappointed so often by loudly acclaimed panaceas which were only exploited schemes based superficially on certain mechanics and which did not reach down to fundamental bed rock, that effort

in the direction of isolating and understanding sound production factors has been retarded.

3. The elusiveness and intangibility of the elements involved have offered real difficulties.

Control Made Possible by Element Identification. The forces which help and those which hinder good results in both desk-work production and factory straight-line production are, in general, the same. The fields are different, but it has been the experience of the research department where these practices are followed that once an element has been made tangible by means of the creation of something to represent it, as a matter of course it submits to the influences which control material objects.

Certain production factors have emerged as those having more than ordinary importance. Brief discussions of these follow.

Attitude of Department Head. Unless the department head approaches his work with the conviction that certain forces have to be understood, and an attempt be made to move with them or avoid them, he will neither search for nor recognize the elements which are essential to achieving the best production. He should realize that while he holds final authority in his department, his responsibility is to develop, coordinate, and lead, rather than to dominate and command. He must encourage and expand the research attitude of the department by careful development of individual opportunity and responsibility. He should endeavor in every way to stay within his personal field of coordinator and leader wherever a member of his department can possibly function as the tool his position permits him to be. As he hopes for success, he must avoid making a "bottle-neck" of himself, thereby reducing the scope of the activities of his organization to where he can personally pass on all details. Such action wastes the individual initiative of his group, which when given freedom and responsibility within definitely limited fields will, in the conscious developments of itself, carry the department forward with much greater force than it could possibly be dragged by the executive himself.

Identified Work Unit the Instrument of Control. Line factory production depends upon the controlled movement of work units. Controlled movement in any production cannot exist without something to control.

It should be emphasized that any inhibitions of complete freedom of individual thought within the limits of the scope of an assigned field is antagonistic to the very idea of research. Control is achieved through assignment to definitely bound fields, rather than to detailed direction of thought or action. If the field is so broad and the direction of the objective so obscure as to indicate the need of a survey to allocate and define an objective, that, of course, should be done. But in the field where the technique of orderly problem solution is being applied to the support of management and where technical engineers and scientists are looked upon as specialists, the objectives of most of the projects can be determined with relative ease.

The instrument of control in production development is the isolated and identified work unit. A work unit is defined as being composed of an element or a group of elements, which can be logically assigned to one individual for development. Once these units are isolated, identified, and made tangible

through the creation and by means of definitely numbered jobs to represent them, the relative ease with which the advantages, similar to those accomplished by factory line methods may be secured, is striking.

Something Tangible Should Represent Each Identified Unit. This is obvious. The form should be easily applicable to a workable plan designed to secure an orderly determination of priority.

In the research department where these methods are employed, every job which requires approximately a half day or more for completion is entered on a job ledger and numbered consecutively. It is set up according to a short, standard form which includes a statement of the job title, its objective, purpose, and the time factor. After approval of the division head under which the work falls and the department manager, the job is assigned to the employee fitted for completing it, and placed by him, under guidance of the department head, in its proper place in the selective line of the employee's work where it waits its turn for attention. No clerical work is needed in the maintenance of the priority machinery, since it is changed by simply shifting the loose leaves backward or forward.

In order to maintain complete coordination, it is necessary for the department head to authorize creation and close of each job. The responsibility for job priority never rests directly upon the employee doing the job. That is, without question, a responsibility of the management; and when such responsibility is imposed unsoundly upon the individual who is actually producing the work, his mind is bound to function less clearly under the unfair strain.

Effort is made to impress each worker with the fact that mechanics have no merit except as they meet the need of some fundamental requirement. Mechanics are but tools; means to an end. When the picture of the fundamental need becomes dim, and the tool is not instinctively reached for, once its utility is established, it becomes a menace instead of an aid. The reason so many "systems" are disappointing is because too much attention is paid to trying to meet the need of certain sets of mechanics and not enough to isolating and understanding the forces which are causing trouble.

The cost of maintaining the method of control in effect is almost negligible. An average of a half hour's typing a day, and an hour's time of the research manager's secretary, is all that is required.

Avoidable Misunderstanding Causes Extensive Pay-roll Waste. After a job is identified, the task of achieving a common understanding among all connected with the important phases of a piece of work is the first obstacle to be overcome in getting a research project into healthy motion.

The person who authorizes work in a research department should know before making an assignment:

1. The objective of the problem to be solved or the work to be done.
2. The purpose, or what the work is to be done for.
3. The requirements of presentation.
4. The time limit within which the work must be finished.

Unless the department head has a clear idea of these things he cannot expect the worker receiving the assignment and who has had less contact with the originating necessities, to guess at them.

If the amounts of money spent in doing work over because of misunderstanding on the part of workers as to what was to be done, as well as the losses incurred on account of failure to receive the needed material on time, could be known, we would probably be staggered by the immensity of the total. Assigning any non-routine work without complying with reasonable necessities of common understanding is like placing an individual at the junction of many roads with insufficient direction. Having to retrace steps and start over means waste and delay.

The possibility of misunderstanding is all the more likely because none of us speaks exactly the same language as another. Though we use similar words, we have lived into them certain individual experiences and are to an extent talking in those experiences rather than in words. Even the most careful discussions wherein all concerned honestly think that they have achieved identical mental images, often eventually prove to have resulted in misunderstanding. A forceful and well-directed attack on vagueness at the beginning establishes a precedent in each job, as well as contributes to a constructive atmosphere in the department. Therefore, it is necessary where there is a possibility of misunderstanding, to take the precaution of having the worker outline briefly in writing his conception of the major requirements of a job assigned him, and submit this outline for approval before beginning actual work. The assignor can then tell with a much greater degree of certainty whether common understanding as to essentials has been reached.

It is true that busy executives should have their requests carried out with a minimum of explanation by them, but no one objects to approving a blue print, and this procedure is but a part of the equivalent of a blue print. The necessity for exact understanding in planning material things is accepted as a matter of course. Once the saving of time and money that can be effected in desk work production by a reasonable and logical precaution of an assurance of understanding is realized, the procedure is looked upon as is any other sound production plan. It is, of course, the responsibility of the head of the research work to see that this plan is used with intelligence, requiring its application only when it is logically indicated, and not simply for the purpose of following out a set procedure. Such would be "red tape," the untiring enemy of sound production.

The supervisor should, therefore, realize that reaching the experience of the worker is his job and the first important step in his effort to improve production. It rests solidly upon the fundamental that the first requisite of being able to answer a question is to understand it.

Why Do Workers Hesitate to Ask for Explanations? Some thought should be given to the reasons why workers in subordinate positions hesitate to press questions with a superior. Human nature comes strongly to the front here. None of us wishes to appear slow of apprehension to a person who holds our economic welfare in his hands. We are all inclined to pretend to understand before we do, trusting to luck and our ability to figure things out. Knowing that this is a human trait, and a very understandable one, it is necessary that precautions be taken to counteract it.

The absence of a common ground of understanding between supervisors and workers as to what is to be done and as to what is possible and what is not, has been the ruin of countless young men of potential executive ability. It is hard to conceive of a more hopeless situation than that in which an employee finds himself when the impossible is expected of him because reasonable necessities enabling him to understand have not been complied with, and who is judged mentally inferior and lacking in capacity because of such a circumstance. The expression "What's the use?" must have first been uttered by an employee in this situation. Officials bemoaning the lack of material for high executive positions might well give some attention to the wanton crushing of budding potential ability by needless misunderstanding.

Conflicting Demand, a Powerfully Destructive Force. Another great enemy of production is conflicting or unsound demand. A conscientious worker, loaded beyond reason or good judgment and harassed by impossible time factors that would be considered ridiculous in a shop where the elements worked upon are visible, finds himself unable to deliver reasonable production in either quantity or quality. A worried mind cannot think so constructively as when unperturbed, for in addition to being burdened with a hopeless resentment because of unfair conditions which must be endured on account of economic necessity, it is instinctively defending itself from criticism. Where these conditions exist, it is not always because management is ignorant of the situation and does not vaguely deplore it, but because it fails to see how necessary and how relatively easy it is to provide each job, or important element of each job, with an identity and something tangible to represent it. No foreman expects a mechanic to repair two motors at the same time; neither will an executive expect an engineer or desk worker to accomplish the equivalent of doing two things at once if jobs are identified and placed in orderly priority for execution. From the standpoint of production development, there is no difference between subjecting a group of mental workers to conflicting demands, or to demands with impossible time factors, and committing a shop organization to produce more good jobs than is physically possible.

Of course conditions sometimes arise where there is insufficient time to do a job properly. In such cases no harm comes to an organization if this fact is accepted and the best job possible under the circumstances is all that is asked for. Such conditions are often valuable, in that they frequently develop new wells of capacity due to the stimulation which comes from a *desire to rise to an emergency for which the workers know they are in no way held responsible*. Where, however, due to conflicting demand and impossible time factors, the worker is forced to feel that his ability is being questioned unjustly, due to conditions concerning which he is helpless, destructive forces are more than likely to do tremendous damage.

Vast sums are being expended by industry for employee health maintenance and reclamation. So far as is known, no attempt has ever been made to measure the losses due to deterioration in physical health caused by worry from avoidable conflicting or impossible demands for which employees, though in no way responsible, have had to bear the brunt. The total of this cost would be extremely interesting and perhaps shocking.

If supervision has any job at all and if there is a line that distinguishes its responsibility as differing from that of the worker, it is to indicate exactly and bound the fields wherein individuals are to work.

Conflicting demand may come from many sources including actual and unforeseen emergencies, but principally from two:

1. From the individual or authority in charge who unsoundly assigns numbers of jobs with conflicting time limits. This usually places the workers in defensive positions and under the necessity of attempting to explain what really are impossibilities without actual measures to prove their cases. The cause of this condition can usually be attributed to the failure of the department manager to have a clear knowledge of the relative importance of the line of work units from which selection for priority is drawn, or to the neglect of using sufficient care in the assignment of individual jobs. The result is that the department head is faced with continual emergencies which compel frequent and ill-timed changes in his program. In either event, it is the equivalent of the repeated loading and unloading of a wagon and jerking the heads of the horses who are endeavoring to pull the load. The result is an atmosphere suggestive of deficient workmanship, and a consequent reaction of hopeless resentment on the part of the workers.

2. Conflicting demand arises from the needs of workers who must rely upon supporting individuals or specialized divisions for material needed in the prosecution of jobs assigned to them. An example is a statistical division being pressed for statistical support by a number of engineers each clamoring for service at the same time, and exerting all the personal pressure they can to get it.

Such a condition is not only the mother of confusion but also of destructive forces of great power. Unless there is a method of coordination and a logical handling of job movement through rigidly adhered to priority channels, those in charge of the specialized divisions find themselves at the mercy of conflicting demands that are demoralizing. They are supposed to maintain a practical cooperation, but it is obviously impossible.

Unless conflicting demand is made impossible, the more pressure that is put upon engineers and others who depend upon the support of specialized divisions, the more confusion results. If there is no general orderly movement as to how all jobs, supporting and otherwise, shall proceed, the engineer has no alternative but to do all he can and exert all of the influence possible to secure the material he needs. Thus, instead of a cooperative group whose thoughts are directed toward a cohesive achievement, there is an individual conflict which is seriously destructive.

The Value of a Wholesome Atmosphere. The human element is considered herein solely as part of a production machine. Reference is made to this fact because it may appear that some of the things believed to be essential might seem to unduly favor employees. It is earnestly desired, however, that there be no assumption that humanitarian impulse had undue weight in reaching the conclusions offered. On the other hand, the cold-blooded necessity of transforming a pay roll into the utmost production that can be gotten out of it has dominated. There has been, however, a serious effort properly to evaluate as many contributing factors as possible.

The question of incentives cannot be discussed here other than to emphasize the fact that only from the employee who feels he is actually working in accordance with his best personal interests can healthy production be expected. But even the most completely contented and enthusiastic worker needs the stimulus of a healthy pressure. The necessity for this pressure has not been overlooked. There is no more powerful instrument for exerting whatever pressure is required than the use of production methods where the worker has no opportunity for evasion and must work on a single work unit, rigidly held in place by a central agency for determining job priority.

Pressure is looked upon, however, as something to be fitted as is wholesome to each individual. Indiscriminate pressure is bound to be confusing and destructive. Some men work best and thrive under a pressure that would leave others confused and impotent. Whatever pressure is applied, however, should be constant and even, and free from confusing or disconcerting elements.

Life is made up of effort to overcome obstacles. Most, if not all, thought is for the purpose of solving some problem. A department should serve as a practice ground, and its work should be practice material for employees to solidify a sound technique in handling problems. Every effort should be made to keep employees continuously conscious of this. They are thus increasing their chances for success in life, which is, in general, dependent upon the ability to make more hits than misses in the effort to cope with difficulties and accomplish development.

INDUSTRIAL DIAGNOSTICIANS

By WALTER N. POLAKOV, *President, Walter N. Polakov & Company, Inc.*

To present, with any degree of clarity and brevity, as complicated a subject as that of relations between consultants and industrial executives, it seems advisable to start with a brief retrospect of the history of such relations since the science of management made its first appearance.

Upon this background it will be possible to outline the present and future relations between the consulting specialist in managerial technique, and the industrial executive, more or less objectively. The pertinent questions in this connection are:

1. Has a specialist a place in modern industry?
2. If so, what relations between the consultant and the executive would be conducive to best results?
3. What tactics and what technique should be employed under such relations?

Retrospect. The year 1903 may be fixed as an official date of birth of scientific management, because Frederick Taylor then presented before the American Society of Mechanical Engineers his paper on "Shop Management," and H. L. Gantt, his two papers on "Graphical Daily Balance in Manufacture" and on "Modifying Systems of Management," although two years

earlier he had already presented another classic on "Bonus System of Rewarding Labor."¹

The aim, the principles, and the method of these two pioneers in scientific management, were so different as to be almost antitheses. Taylor's aim was elimination of soldiering and making workmen personally efficient. Gantt's aim was elimination of waste time resulting from managerial maladjustments, and to make the executives personally efficient. Taylor's method was that of centralizing and functionalizing control, while Gantt's method was that of giving necessary information and authority to the shop foreman. These cardinal distinctions flowed, with logical necessity, from the principles postulated by each, viz.: the autocratic control postulated by Taylor, in contradistinction to democratic leadership postulated by Gantt.

The technique and the mechanism devised in each case were equally dissimilar, but the practice of introducing them involved, in both cases, actual installation of method and training of personnel, for at that time, naturally, there was no contingent of men in the employ of the firms undergoing this reorganization, versed in the technique, or even fully familiar with the principles involved.

The job before these and other pioneers in the field of scientific management obviously involved the task of installing the whole system; of demonstrating that it worked; of overcoming inertia; of breaking precedent; of displacing tradition. Like pioneers they had to clear the ground before they could till; they had to wreck the old building before they could erect a new edifice. They may have appeared intolerant and dictatorial, almost fanatical, without being at all so by nature. They had the vision, the message, and the means to realize it; but the men with whom they had to work, often the executives of the client firms, had only a scant idea of either principle or methods. These executives were chiefly after quick and spectacular results. They were the executives of an old school, prone to be autocratic and dictatorial, having little patience for research, often led in their decisions, if not by personal whims, then by debates and votes. The habit of relying on tests and computations had not as yet been formed.

In those days, every detail of installation work had to be done by the organizer, by the expert, and as these were too complicated and numerous for one man, consultants had to have a staff of assistants and understudies; the larger the staff, the greater was the impatience of the client firm for the financial returns.

The "Efficiency Expert." The financial returns were not slow in coming. The classic examples of greatly increased efficiency under the scientific reorganization, promptly tempted scores of untrained, self-styled efficiency experts to offer their services, and knowing little beyond the rudiments of time studies, they pinned their faith on imitating forms, blanks and collections of tricks, by means of which they hoped to place industry on a higher plane of efficiency.

The reaction against this fad was not long in coming. A cartoon on the editorial page of a well known contemporary newspaper recorded the public

¹ American Society of Mechanical Engineers, 1901.

attitude at the time. Asked the girl, "What's an efficiency expert, Harry?" and the man replied, "Oh, anybody who can teach you how to do something he doesn't know anything about himself."

As early as 1913, Gantt voiced the more serious attitude against this movement in these unmistakable words:

The man, who undertakes to introduce scientific management and pins his faith to rules and the use of forms and blanks without thoroughly comprehending the principles upon which it is based, will fail.

The antagonism against the indiscriminate and incompetent use of the stop watch found its expression in the act forbidding the time studies on government employees.

The well-known investigations conducted by various civic and political bodies and capable investigators, such as J. P. Frey, Louis Brandeis, and others, finally succeeded, in a large measure, in checking the activities of self-styled imitators and so-called efficiency experts, who frequently had no other background than a smattering of accounting or office experience.

Demand for Staff Engineers. As the new movement was living through this period of trials and tribulations, the undisputable benefits of management engineering to industry during the first quarter of the century became apparent not only in the isolated cases of individual concerns, which changed their mode of management, but in the industry as a whole. This true value of the principles of scientific management applied to industry, and the tangible results accomplished by serious men in many well known instances, created a definite and insistent demand on the part of industrial executives for competent men, thoroughly trained for detail work in industrial engineering and management engineering. Firms of efficiency engineers emerged, with large staffs of first-, second-, and third-rate men and the profession ran the risk of becoming commercialized, assuming the complexion of "contractors." This period was short and large organizations of such nature were gradually disbanded, for economically, psychologically, and ethically, they were moribund.

Thus it behooved the engineering colleges and business schools to prepare and provide such cadres of detail-study men to assist the executives. Soon men with appropriate diplomas appeared on the labor market, and found employment in the concerns who were in the habit of buying ready-made goods on the cheap market.

This created a new phase in the situation, insofar as relations between specialists and executives were concerned. A college-graduate management or industrial engineer, even if well informed as far as textbooks and laboratory work are concerned, naturally had little or no practical experience. At the same time, their avowed aim was to revamp and improve the most important and complicated department of all the industrial activities, namely, that of organization of management. The internal contradiction of the situation was rapidly apparent. On the one hand, the executive, employing the college-graduate industrial engineer, still had to dictate to him the policies and define the principles and the tactics, expecting him merely to dig into his bag of tricks to solve this or that isolated problem. On the other hand, the col-

lege-graduate management engineer, by virtue of his job, had to criticize his own boss, or even to expose his employer's incompetence. Small wonder that these attempts at self-reformation left many bitter memories, and only as these young college men themselves became responsible executives, did the anomaly of the relations begin to adjust itself.

Present Need for Specialists. The complex relations existing in modern industry can hardly be compared with relatively simple set-up of manufacture of half a century or even twenty years ago. The technology involved in most processes developed to a point where each small branch can hardly be mastered in one's life time, especially in view of rapid and ever increasing progress. The personnel problems likewise grew in complexity. Social and recreative activities, hygiene and safety, including ventilation, illumination, proper postures, psychoanalysis, and so on, are themselves almost infinitely complicated. Economic relations, wage payments and incentive plans, buying and selling, financing, accounting, etc., is but another little corner of the field, but how immense! And now the managerial technique itself—that of coordinating the functions, influencing the actions, setting tasks, scheduling production, recording accomplishment, and so on—is indeed a rich and vast field for specialization.

For an executive in modern industry, confronted with such problems in the specific relation to his particular line, even to assume that he may know all and be reasonably successful under the competitive conditions, growing keener every day, is to exhibit a lack of sanity. He must depend upon advice and information provided by specialists in this or that branch. The inevitable tendency of larger corporations of today is, therefore, toward research and permanent employment of specialists in various branches of technology. The smaller corporations, obviously, cannot afford the overhead of a large staff of specialists, permanently employed. So far as technology of processes are concerned, they, perforce, limit their activities to avoid spreading over a large field, but from time to time, whether because of the progress made by their competitors, or due to the market pressure, they are forced to make further improvements or add a new line of product, and the resort to a specialist's advice is inevitable. Even if we assume a corporation of gigantic proportions, with unlimited financial resources that could not be overtaxed with an army of specialists and experts, the situation cannot be altered in such an instance. For, having in their permanent employ the staff of specialists, whose services may be called for but seldom, these long intervals between their activities are bound to diminish the value of their service in the same way as the dexterity of a musician or a doctor diminishes if he remains for a long time without practice.

In a word, modern industry today largely depends upon the knowledge of highly specialized men but only exceptionally large corporations can keep them permanently engaged. Hence—a need for the consulting specialist.

Thus the very nature of our rapidly developing industries, continually pushed forward by great discoveries of science, makes the employment of specialists today more urgent than ever it was, and what is true in respect to specialists in technology, is far more true in respect to specialists in managerial analyses and technique, for the sciences from which the management

specialist derives his tools, are both younger than technical branches, and make faster, though probably less spectacular advances, by leaps and bounds.

This fact is generally recognized by the industrial leaders of vision. The executive positions today are more frequently filled by engineers than by lawyers, bankers, and men vaguely defined as "business men." These, being specialists well versed in the nature of production or operations in which their firms are engaged do fully appreciate the worth of specialized knowledge. The same applies to the superintendents, plant engineers and foremen. It is their desire to secure the results compatible with their knowledge and ability that would be to their credit. Hence they welcome any effective measure to eliminate all administrative, managerial maladjustments that may hamper their free and efficient functioning. Hence they welcome the services of a competent management consultant within whose province it is to remove the obstacles hampering their work.

Moreover, under these changed circumstances the executive of today no longer fears, as his old-fashioned predecessor did, that an invitation of a management specialist would cast a reflection upon his own ability; quite the contrary, having no respect for "jacks of all trades," they have no patience with amateurish dabbling with managerial functions and prefer to "call in a specialist."

Even if an executive is not a production man and technologist, but a management specialist himself, the very fact that he holds an executive position puts before him a dilemma—either to capitalize the old stock in trade, and base his decisions upon the rule he has worked out sometime ago, when he had time to study problems as they were then and there, or to defer the executive action until he could arrange enough leisure and sufficiently disentangle himself from daily problems, to study this or that situation with the thoroughness it demands. Obviously, neither horn of the dilemma is an adequate procedure for a man who realizes his responsibility to the firm that vested him with authority. Neither can he, in the important matters, relegate fact finding, thorough study, and careful coordination to some junior member of his staff. In other words, there is no alternative but to "call in a specialist."

Under this changed industrial set-up, it is reasonable to expect that the functions of a management consultant and his relation to the executive would be different from those of yesterday.

New Form of Relations between Executive and Consultant. Let us consider now the form of relation between management consultant and industrial executive that is forced upon them by this new industrial orientation. To begin with, a few terms should be defined in order to gain clarity and uniformity of understanding.

In the first place, let us define management as a process of releasing and directing human energies toward attaining a definite goal. By accepting this definition, the danger of confusing management with a body of certain rules, forms, and practices, will be avoided. Management, as a great form of human activity, thus defined becomes comparable to the term "science," which likewise is not a body of knowledge, nor a record of achievements, but a process of acquiring ever more and more complete and exact knowledge, and

establishing categorical propositions. Scientific management, therefore, will be that kind of a process of directing human efforts which employs the scientific method, and the management specialist, hence, could be defined as one who specializes in application of modern scientific method to the solution of the problems arising in the process of management. Similarly, the term of "industrial executive" denotes a person who executes, or causes to be executed, the managerial programs.

It is clear, therefore, that the relation of the management consultant to the executive is that of rendering counsel. The nature and the scope of the counsel is, obviously, determined by the competence of the consultant in a specific field. Stated in other words, the task of a consultant is to analyze a problem, and to advise as to the best course of procedure, while the task of an executive is to execute the plan. Thus boldly stated, the relations may be misinterpreted to mean that the executive is not expected to do anything but what he is told to do. Nothing can be further from the truth. By being informed as to accurate facts, his freedom of action is no more limited than the freedom of action of a fireman is limited by the pressure gage, or that of a passerby by the sign, "Wet Paint." By neglecting the competent counsel, we are licentious—not free, and leave many a finger print on the fresh paint. By observing it, we exercise the freedom of acting rationally. The fascination, the joy and satisfaction in the executive work, and pride in the accomplishment, lies not in securing of information, but securing results by acting upon reliable information.

Hence, in his relation to the client firm and its executives, the management consultant does not assume any of the executive functions. Even as a medical consultant, he cooperates with his colleagues on the hospital staff, or holds a council with the family physician. He realizes that their knowledge of this specific case, that their evaluation of certain symptoms, that their familiarity with constitutional weaknesses and idiosyncrasies, are of paramount importance for arriving at a correct diagnosis.

When diagnosis is thus made, the next move is to prescribe, but a consulting physician does not perform an operation indicated, neither does he administer a patient's diet and general regimen. This parallel is true again in case of a management consultant. Once troubles are disclosed, their relative importance established and procedure agreed upon with the client's experts, it is up to the executives and their staff to institute such changes as may be indicated. It is their function and responsibility; it is their pride to attain success; it is their duty to see to it that the plant is functioning right, and, above all, it is to be remembered that they are experts in their respective lines. To interfere with their betterment work would be comparable to interfering with parents in bringing up their children. It is to hurt their feelings and accomplish no good.

But a consultant does not yet fold his hands. He watches carefully the records of progress and further diagnoses its indications. The keynote of this work may be termed as "preventive engineering." The elimination of waste is important, but it is of no avail unless the means are evolved for preventing their recurrence in the future. The elimination of administrative maladjustments and incompetence is important, but it is of no avail unless the

organization is permeated with principles that will prevent sliding back into the old rut. In the past there was no alternative for the management specialist but to bring along a staff of his own to make these studies and actually install the new method in every detail, whether with or without the cooperation of minor executives of the client firm. Like a mediaeval doctor, he had to be his own assistant, the barber, the nurse, the masseur, and the druggist.

It was only natural that under the old forms of relations, the "systems" installed by the outsiders would eventually disintegrate and fall into disrepute. The cause for it can easily be found in the old contract system of "installing management methods." Disintegration was usually due, first, to the fact that whatever was done was considered by the members of the client firm as an importation and imposition. It was something foreign to the personnel of the concern; its reason and advantages were perhaps not clearly understood; its operation was, for a long time, unfamiliar to them, and hence appeared as cumbersome or useless. When these new functions were finally turned over by the staff of the expert to the personnel of the client concern, they were most likely performed perfunctorily, imperfectly, and benefits therefrom were slight, if any, until these "fancy" things were finally abandoned. Second, whatever may have been done by the outsiders was naturally subject to "watchful waiting," sometimes provoking criticisms, at times snickers, and perhaps even antagonism or open hostility. Thus a measure, however good and sound, had psychologically a negative reaction; the personnel could never take pride in it, for it could not regard the improvements as its own achievement. Consequently, having no tie of any kind—mental or emotional—to the new fangled importation, the personnel, as well as the staff, if they were earnestly seeking better ways, continued to try now one and now another new stunt, until the whole managerial structure became full of patches, props, and dabs of paint, incoherent, poorly dovetailed, sometimes appearing as a most curious conglomeration of strange ideas and devices.

With the new relations of a consultant to the executives and the staff of the client firm, such gruesome fate is quite unlikely, for once a proper functioning of management is organized, it forms an organic whole with the entire structure of the firm.

Today, with rare exceptions, the managerial force of a client concern comprises members quite competent to carry on both studies and installations according to specifications and under the general guidance on the part of the counsel, whose functions are thus more comparable now to those of a medical specialist diagnostician. In this respect, the position of management consultant has changed greatly. He is no longer a contractor, who guarantees to secure results. He is strictly a professional man, who diagnoses the situation, and prescribes the régime and treatment.

"Catalytic" Action and Tactics. There is another big phase of the relation between the management consultant and the staff of the client firm, which may be called, for the want of a better expression, a "mental catalysis." The very fact that the firm has engaged the services of a reputable engineer acts as a subtle, yet often powerful agency for the release of dormant energies, valuable ideas, greater interest in one's work, fuller cooperation with the main

office and keener competition among departments in producing commendable results. It is indeed very similar to catalytic action speeding up or promoting reactions without the catalyst itself being absorbed or changed.

This stimulating, catalytic faculty of a consultant is almost as essential for the success of the undertaking as another, namely, tactical ability of the consultant to disclaim his "authority" to impose anything, but to establish the relation of confidence, for to understand is to be understood, and, it cannot be overstated, the major part of his work is with the human element, not with machinery, processes and records. When this is accomplished, the executives and the rest of the client's personnel prove themselves in general qualified to introduce with understanding all the desirable changes and improvements. Of especial importance, is the fact that the good results thus accomplished by members of the organization furnish the personnel with interest and pride in their work and tend to perpetuate a high level of efficiency, once it is attained by them.

Indeed, in numerous instances the executives and the engineers of client-firms proudly present before professional societies papers describing the progress made, or publish articles, freely giving credit to consultants. Even with gradual change of the entire personnel of some departments, the once introduced amelioration persists by tradition and years after the introduction the habits of industry and high standard could be found, if anything, further advanced.

Methods of the Consultant. Viewing the work of a management consultant from another angle—that of his internal working process—it appears today vastly different from the well beaten path of the past.

The management consultant, content with the old technique and old processes of thought is as much a back number as a voodoo doctor or alchemist. They are still "scientific" in a sense that they aim to establish categorical propositions but they are establishing them largely upon the premises since rejected as fallacious.

Today a consultant management specialist, in order to be a diagnostician, should be primarily a logician. His first step is that of detecting the postulates upon which a given managerial doctrine is based. If the client-executive holds doctrines logically incompatible with these involved in the modern theory of management, he may be left alone as doctors leave alone the "incurable"—the best that can be done for him is to allay the pain.

If there is a hope, *i.e.*, if a client-executive maintains a doctrine with undefined or assumed terms which can be clarified, defined and proved for him, then the rest is a process of a logical necessity and the results follow inevitably, as a matter of destiny—a logical destiny, of course.

The next step is then to stimulate the creative thought of the client-executives. By that we mean to set their imaginative power to work, to visualize the desired course and the aim. Third comes the long and painstaking logical analysis of "what is" or present inconsistencies in practices, methods and results. These must be proved false or meaningless (not merely stated) and from that proof the new course will take form.

Then comes the fourth stage of the "inside" work—that of coordinating and directing efforts toward the desired goal. In this work nothing is kept sacred or unalterable save consistency of actions with the defined aim.

It goes almost without saying that the consultant's job of "directing efforts" is in itself a two-stage process. The first stage may be termed as priming, during which, by means of broad discussion of principles, illustrated by similar applications elsewhere, and careful demonstration of adaptability under the particular individual conditions, the recommended method is presented to the executives, and its working advantages are clearly understood in the main, and the desire to inaugurate this change is created.

The second stage of this cycle is the working out in all details a complete specification in writing of actual adaptation of the method recommended, with the detailed recommendations as to persons in charge, their duties, responsibilities, process of work, special equipment, means of recording and accounting, procedure of follow-up and maintenance, methods of computation or inspection, etc.

Of course in some instances the first stage is unnecessary, while in some other instances the second stage can be safely left to the executives themselves, depending upon the nature of the measure and the characteristics of personnel affected. Here is again the apt parallel with the practice in the medical profession. The specialist in preventive medicine prescribes a certain immunization, a method of application, for instance, of toxin antitoxin, and in some cases, perhaps, gives the complete instructions as to preparation of this antitoxin. But he does not usually himself perform the injection or vaccination. Even in curative medicine, the physician prescribes in all details the compounding of drugs, but it is left to a pharmacist to fill the formula, and to the nurse to administer it to the patient.

From this brief sketch it becomes apparent that the present-day management consultant acts in four departments of human endeavor:

1. As a logician he practices the art of critique.
2. As a psychologist he exercises power of suggestion.
3. As an engineer he directs forces and devises means.
4. As an economist he evaluates results.

The question, how the functions of the consultant can be performed, is now practically answered. It is evident that such an enterprise as diagnosis of industrial troubles and direction of their elimination is a work for an individual, not for an impersonal institution or a group of men organized for such service by a resourceful entrepreneur. Such work is based essentially on personal contact, on good judgment, mutual confidence, and hearty cooperation.

The "short cuts," cut and dried rules, ready-made formulas and whole array of stunts and tricks could be taught by a correspondence school, temptingly narrated in magazine articles and related at the meetings and in the clubrooms, but they do not constitute the substance of that service which is expected of a consultant—an industrial diagnosis.

The Industrial Diagnosis. Since he is primarily a diagnostician, the first function of a consultant toward indicating the practical procedure, is to establish definitely what interferes with the best possible performance of the proper functions of an organization and how to remove the obstacles.

This demands, at the outset, a triple analysis:

1. Are the orders filled on time and in proper sequence? If not, why not?
2. Is the equipment used or idle? If idle, why?
3. Are the men doing their work in the best possible way? If not, why not?

These queries lead to further inquiries:

If part of the equipment is idle part of the time, why? Is it because of lack of orders, lack of material, lack of men, lack of power, poor repair? How much does it cost to own idle equipment, and what effect has it on the cost of product? What part of the idleness is avoidable and how can it be avoided?

If men are not doing a "fair day's work," why? Is it because there is not enough work, or lack of work material, or machine breakdown, or poor tools and supplies, or lack of instruction, or poor practice? Is there any measure to gage the output of each man or each group? If not, why not? If quality and not quantity of work is the deciding factor, is there any standard to compare with? Are there any incentives to do more or better work?

Such are but a few general questions to start with; but the consultant is neither a detective nor a mere record clerk. He formulates the questions that are pertinent; then he proposes the technique of securing dependable answers, but it is the executive's task to furnish the requisite data. A medical consultant does not doubt the family physician's report as to patient's pulse, temperature, blood pressure, urine analysis, etc., as it has been observed for weeks—he draws his conclusions and states probable cause. A management consultant should not attempt any more, for otherwise it may be regarded as an insolent lack of confidence in the intelligence of the client's staff.

At last he outlines the procedure, the régime as it were, of removing obstacles—i.e., inaugurating the practice of the "preventive engineering."

The most effective tool as yet devised for the practice of "preventive engineering" and direction of production is based on the four-dimensional, or non-Euclidean system of chart analysis, first described by the late H. L. Gantt, and further developed by Wallace Clark and the writer.

With the aid of charts, simple enough in their technique to be handled by departmental foremen and their clerks, most of the work that would have to be done by "staff" is so much simplified as to require no additional help.

True enough, in a number of industrial establishments it is sometimes difficult to find men who are not overburdened by their routine duties to a point where it seems impossible to ask them to do a thing more or to pause a minute for a mature and quiet thinking over the situation. But bringing in several or even a score of "assistants" for doing detail work of installation of a new method means often a disruption of an organization, and it is far better to employ directly capable men who, being free from routine duties, could work without hindrance under the consultant's guidance.

Group Consultations. There is one more peculiar form, or rather a variety of form, of relation between the client firm and consulting specialists. We have in mind the so-called group consultation. What is it, and how does it work?

Consider a firm that has come to realize that their accounts do not disclose with adequate clarity the sources of their troubles; that they have also learned of their competitors having just developed a new process; that they know that their own power department is lame and that their wrapping is being criticized on the market, in addition to a certain conviction that their managerial technique is antiquated and many of their minor executives and other employees are irritable and perhaps misplaced.

Can any one specialist help them competently in all these lines? Decidedly not!

Such a situation would obviously demand group treatment. An accountant will have to reshape the system of accounting; a chemist will have to surpass by his research the competitive improvement; a power engineer to modernize the power plant methods and equipment; a machine designer to develop an automatic wrapping machine, and a psychiatrist to analyze the misplaced and irritated employees.

Can all that be done by all these men, however competent, independently of one another? Such a fortunate outcome would be highly improbable, for an accountant may not be informed as to new rearrangement of processes and abolition of some departments and operations as the result of work of a chemical technologist; the power man may overlook the proposed change in the demand for this or that form of power; the psychiatrist may try to allay the trouble in the department which is about to be abolished; while the machine designer may overestimate, or otherwise, the future output. Their work, of necessity, should be carefully coordinated, preplanned and scheduled. All pertinent information should be made available and the relative importance of each trouble accurately evaluated. Such function may be performed by the chief executive of the client concern, but, to do so, he would have to resign as the executive to devote his undivided time and attention to direct this reorganization. A specialist in management installation would, most assuredly, be the man to assume the responsibility for such coordination of work of a group of specialists.

But, if so, a question may be asked: Is it not reasonable to expect that a group of specialists in such various branches of industrial betterment may be permanently incorporated to be ready to render their co-ordinated services? Such an assumption is not warranted by fact. In order to render satisfactory services each member of this group of specialists should command the confidence of the client, *i.e.*, should be selected by him, not by an entrepreneur. Then again, men of great experience and professional standing are not available for regular employment by a consulting firm, placed on the pay roll, subject to regulations and discipline, etc. Moreover, a group like this, even if assembled and working smoothly, must be continually kept busy, obviously no need for all of them will be present in every case. This would involve national advertisement, extensive solicitations and other heavy sales expenses. Leaving aside the question of professional ethics involved in such salesmanship, the overhead would be staggering.

Yet it is undeniable that the complexity of present-day industrial problems demands specialists—advisers—and with the rapid development of science

and equally rapid expansion of industry no one specialist could render competent service in the multitude of branches.

Summary. To sum up the salient points of this brief outline of relations between management consultants and industrial executives, the trend appears historically away from the relation of a contractor undertaking an installation and toward diagnosing professionally the causes of troubles and advising the course to be followed by executives. The arguments favoring this trend actually observed in practice are: economically that it is more efficient to secure competent advice and scientifically correct analysis and prescription than to blunder accidentally into the correct path after much floundering around, or to fit in a practice developed elsewhere; socially, that with complexity of present-day industrial relations and great development of technical and other sciences specialization within specialty is inevitable and appears the safest way to success; psychologically, that the more competent is a man in his own sphere the more anxious he is to consult with competent men in another field; that practice wished upon is less likely to be followed than one developed in friendly cooperation; that such joint development of improved managerial procedure stimulates striving for perfection as catalysts stimulate chemical reactions.

The recorded facts concerning such a mode of relations indicate their soundness in so far as such new managerial technique and its results frequently are reported by executives in press or before professional meetings with due pride and the new practice is invariably retained in use, perpetuating itself for as long as records reach back.

Professionally such relations lead to the establishment of a new branch of engineering and managerial science—we call it “preventive engineering”—which involves precise logico-mathematical method and aims at the prevention of various forms of industrial waste rather than the cure of this or that maladjustment or ill practice in each single instance.

THE ECONOMIST AS AN AID TO MANAGEMENT

BY L. D. H. WELD, *Director of Research, McCann-Erickson Company*

There are economists and economists. Their value to business concerns depends both on their personalities and on their particular lines of training or specialization. In a sense, all economists are an aid to business, whether they are engaged in university teaching and research, or whether they have forsaken the academic halls and cast their lots with business houses. Those who are engaged in university work are gradually formulating more and more fundamental principles that underlie business organization and methods, and they are sending out more and more young men who have an equipment of economic knowledge that makes them better business men. It is the economist who goes into business, however, with whom this paper deals.

Economics is a big and broad science. It embraces a number of different branches or divisions, and it is beyond the power of any one man to be an expert or authority in all of them. Just because a man is branded as an “economist” does not mean that he would be of value to the management of

any particular business house. His potential value depends on his field of specialization and on the needs of the business house.

Different Types of Economists. It is therefore time to begin to differentiate between the different kinds of economists, the types of work that they are equipped to undertake, and how they may be of value to different kinds of business houses.

There is, for example, the specialist in economic theory, the man who gives his time and thought to teaching and speculating on the theory of value and prices, the distribution of wealth among capitalists, wage earners, and land owners, etc. He is likely to be of very little direct value to a business concern. Very few of this type leave their academic surroundings. They are not often called into the business world. They are doing valuable work where they are—some of them, at least—but they are a more or less detached lot, and know little of the practical aspects and problems of a going business concern.

There is the economist who has specialized in money and banking. The average manufacturing or commercial house has little need of such a specialist. The best place for him, outside of academic circles, is with a bank. And there are many banks in the United States that have employed such men. They are used in different ways, however. Some build up service departments that are helpful to customers; some specialize on the trend of business conditions and the movements of stock and bond prices and money rates, so as to help the bank in its investment and loaning policies; others specialize on the analysis of different industries and the financial conditions of individual companies, so as to help determine the amount that may safely be loaned to them.

Then there is the economist who specializes in labor problems. He is sometimes engaged by a business house to help in the handling of personnel problems. There is also the economist who specializes in accounting, and he likewise is frequently of value to a business house in his particular field of activity.

The economists who may be of greatest value to the management of a business house, however, are those who have specialized in statistics or in business organization and administration, or in both.

Types of Statisticians. It may be said that there are three kinds of statisticians: compilers of figures, economic statisticians, and mathematical statisticians. Compilers of figures may be found in most business houses. They are often located in, or have originated in, the accounting department. They are men who have shown natural aptitudes for tabulation of figures and records wanted by the executives of the company. Their work is of value, but they are not statisticians in the true sense of the word. They are merely supplying the raw material which the true statistician must analyze and interpret.

The economic statistician is the man who has had fundamental training in economics, but who has specialized in statistical theory and method. He studies statistical method from an economic point of view. If his training in economics has given him sound views on money and banking, on business organization and methods, on advertising and selling, etc., he is the man who can be of value to the management of a business house.

The mathematical statistician is the one who approaches the science of statistics through the study of mathematics. He is interested in statistics because of his love of juggling figures through the use of the methods and formulae of higher mathematics. He generally knows little of economics or of business processes. He has much of value for the economic statistician, and the two together might make a good team; but the mathematical statistician can be of little direct value to a business house, except as actuary for an insurance company, unless he has the opportunity and the disposition to overcome his lack of knowledge of economics and business methods. There are men who have done this successfully.

It is difficult to draw the line between the economic statistician and the business economist, because each must have a wide knowledge in the field of the other. No statistician can be of the greatest possible benefit to a business house, unless he is well grounded in business methods, sales policies, etc. Likewise, the business economist can not get very far without having recourse to a generous use of statistics. It will therefore be possible to treat the two together, in trying to answer the question: How can the economist be an aid to management? It is understood that we mean the economist who has a foundation of general economics, but who has given special attention to problems of business organization, sales and advertising policy, etc., and who at the same time has a knowledge of statistical methods.

Where the Economist Can Help. The principal lines of work in which the economist may be of value to the management of a large manufacturing or mercantile concern are as follows: (1) sales research, (2) relation to general business conditions, (3) raw material markets, (4) labor policy, (5) relations with the government and the public, (6) advice on general economic problems, (7) foreign trade policy, (8) organization matters, (9) budgetary control, (10) financial policy, (11) general statistics.

This looks like a formidable array of activities for an economist or for a research or statistical department. There are probably no business houses that are seeking expert advice from economists on all of these matters.

The most important matters in which the economist can be of value are the first two—sales research and general business conditions—and it is worth while to analyze more closely the possibilities under these two headings.

Under sales research there are four principal fields of activity, as follows:

1. Market surveys.
2. Consumption by districts.
3. Price trends and policies.
4. Analysis of internal statistics.

Market Surveys. Market surveys involve field work in order to determine such things as percentage of retail distribution, consumer and retailer preference, character of competition, etc., etc. The object of such surveys is to determine the best sales method or to determine the best advertising policy, or both.

For example, the commercial research department of Swift & Company was called on to make a survey of a residential district near Chicago in order to determine whether the company should establish a branch sales house in

that section. This meant a personal visit to practically all dealers, finding out the total amount of various products handled, the percentage bought, and who the principal competitors were. It was possible to estimate the total consuming capacity of the territory, the percentage that they ought to be able to get, and the amount of territory that should be included in order to yield enough volume to make a branch house pay.

Practically all large business houses have similar problems. They want to know whether a certain territory should be covered more intensively; whether sales should be direct or through jobbers; whether exclusive jobbers or exclusive dealers should be used.

Consumption by Districts. This means the determination of sales potentials by geographic districts. It does not necessarily mean personal calls on jobbers, retailers, or consumers. Rather it is a development of a statistical measuring stick, or a combination of measuring sticks, in order to determine consumptive capacity. The objects of such studies are, first, to compare actual sales results against possibilities, and second, to furnish a basis for sales quotas.

Sales quotas are coming to be recognized as a valuable aid in sales planning and in the payment of individual salesmen, but it is difficult to determine fair quotas. This is a field where much work needs to be done. There is no uniform method that will fit all industries. Each company has to work out its own method of determining sales quotas. There is usually no single measure that will yield accurate results, and the problem is to find the best combination of measure, such as per capita consumption, income tax returns, number of automobiles, number of telephones, rural and urban population, foreign and native born, etc.¹

The problem is to find the best combination of three or four of these available statistical measures, and the best way of combining them so as to get the most accurate measure of sales possibilities. The method must be simple and understandable, so that it will be accepted by department managers and salesmen.

Price Trends and Policies. This links up with the subject of general business conditions, that will be discussed below. It includes a study of seasonal variations and the possibility of ironing out the sales throughout the year.

Analysis of Internal Statistics. Every business concern keeps sales and sales cost statistics to a certain extent, but a statistical or research department can analyze and graph these figures so as to enhance their value greatly. Sales figures should be analyzed by sections, over periods of time, and by individual customers. Sales costs should be analyzed for the business as a whole, by branches, by departments, etc. Analysis of advertising results also falls under this general heading.

General Business Conditions. Business executives are paying more and more attention to general business conditions, and their relation to the particular industry or house which they represent. The business cycle has come

¹ The author has developed a method of measuring sales possibilities by using the statistical principle of correlation. This method is described in a series of seven articles in successive issues of *Printers' Ink* beginning January 31, 1930.

to be an important phenomenon that must be reckoned with in formulating business policy. Executives themselves rarely have the time or statistical knowledge to study this matter thoroughly or scientifically, and trained economists can be of great help to them. True, there are economic and statistical services that they may follow—some good and some poor. But the various statistical services do not always agree with each other, and it requires a careful comparison and appraisal of the different services in order to reach an intelligent opinion as to the probable future trend of the general business curve.

Furthermore, special studies are necessary within a business house in order to determine its relation to the business cycle. The price of hides anticipates general business conditions in its up turns and down turns; the price of steel lags a little behind. Some businesses are affected more adversely than others by industrial depression. All these things could be studied, with a view of helping executives decide on such questions as the following:

1. *Purchasing Policy.* Goods may be bought for considerable periods in advance if the industrial outlook is good. Otherwise, they should be bought from hand to mouth, and at certain stages in the business cycle purchases and plant production may be curtailed to advantage.

2. *Sales Policy.* When a period of rising prices is anticipated, there is no need of sacrificing goods in order to move them. When there are indications that the crest of a prosperity wave is about to be reached, goods should be moved rapidly, and when prices start downward, after a period of real inflation, goods should be sacrificed, so as to avoid heavier losses in the future.

3. *Storage Policy.* In the case of seasonal goods, the quantity put into storage, and the price that one can afford to pay, depends largely on the probable general business situation at the time of removal. This applies to such products as cured pork, butter, and eggs.

4. *Financing Policy.* A study of business conditions, and especially of the course of bond prices and interest rates, is invaluable in determining the proper policy to pursue in the issuance of stocks and bonds and the best date of maturity of bonds.

5. *Construction Policy.* Boom times are likely to lead business men to use their profits in building new plants, or extensions to old ones. At such a time building materials and labor are high and by the time the improvements are completed, an industrial depression may have developed. This requires expert study and planning.

Let it not be thought from what has been said that definite answers can be continuously given to all the problems mentioned. Business men always have to plan ahead in all these matters, but in the past they have had to rely principally on guess work. Enough progress has been made in the scientific study of business cycles at least to help substantially in formulating proper policies. The business manager, who ignores this fact, is at a disadvantage as compared with his more scientific competitors.

Labor Policies. The economist, with his outside point of view, can be of considerable help in formulating policies which have to do with personnel administration, management of welfare work, etc., and he can supply data on wage rates, and cost of living, which are invaluable in the adjustment of wages.

Another field of endeavor which is closely affiliated with labor problems is dissemination of economic facts and principles among employees. One of the greatest needs of the day is the education of the public along economic lines. This really ought to be done by some large national organization, but must also be done by individual business houses among their own employees, through plant papers, leaflets, and placards, meetings with foremen and employee representatives, etc. Relations with employees may be improved by giving them correct information about the profits of industry and their relation to wages, the relation of one industry to another, the value of large-scale production, etc., etc. The economist can be of great help in this kind of work, although if left entirely to himself the material that he prepares is likely to be too abstract and unattractive for effective use.

Relations with the Government and the Public. This field of activity is of importance to relatively few industries, but it is of very great importance to those few. The railroads and other public utility companies need to be interpreted to the public from an economic point of view. The same may be said of the steel industry, the oil industry, and the packing industry.

Other fields of activity in which the economist may be an aid to management may be described very briefly. As for general economic problems, there are questions of tariff, attitude on immigration, taxation, child labor laws, etc., on which business executives need advice. With regard to foreign trade policy, there are questions of foreign exchange, whether goods should be exported or forced onto the domestic market, to what extent advertising should be done in foreign countries, and the extent to which a manufacturer should develop his own foreign sales organization. The value of an economist's advice on organization matters, budgetary control, financial matters, and in the compilation and dissemination of general statistics, requires no comment.

Research Department. Although a single economist might be of value in an advisory capacity on many of the problems outlined above, his activities ordinarily involve a considerable amount of research work. This means that he must develop a corps of assistants, especially if any considerable amount of statistical work is to be done. The question arises as to the proper place for such a department within the organization, and the name that the department should have.

As for its position within an organization, the department should report direct to the president, or to a vice-president or general manager. Even if the work consists entirely of sales research, the department should not be under the supervision of the sales manager—at least not under the ordinary type of sales manager. It would be all right in this case to come under the jurisdiction of a vice president in charge of sales. The point is that if such a department comes directly under the supervision of the sales manager, the findings and recommendations are likely to be prejudiced and carry less weight with the executives.

There can be no doubt but that economists are in greater and greater demand among business houses. The universities are not turning out enough of the right kind of men in this field. They are helping to supply the need, although most of the men from these schools have an insufficient background

of general economics. Business executives are learning to appreciate the value of sound economic advice and the demand for men with economic training is bound to increase in the future.

TRAFFIC MANAGEMENT

BY DABNEY T. WARING, *Traffic Consultant*

Functions, General. Many executives consider their traffic department of value only in handling shipping details, such as the preparation of shipping papers and filing of claims, and are guided by this thought in its creation and organization. As a matter of fact its value and the field of its activities depend almost entirely on its personnel. Properly managed and equipped, the traffic department is of inestimable value to an industry and at no time in our history has this been so manifest as today. Its value to a small industry is the same, relatively, as to our largest corporations and frequently a firm's continued success, or even its very existence, depends on the functioning of its traffic department or traffic service.

Our transportation system and transportation costs are now undergoing drastic changes. Our waterways and highways have in recent years developed into important arteries of commerce and our freight rate structure is being taken apart and remade. Our industrial map, for transportation reasons, is constantly changing. The importance, therefore, of keeping fully informed with respect to these vital matters is at once apparent and the traffic manager or advisor is the only reliable medium through which it may be done. The field of traffic management, or traffic profession as it is now generally called, is necessarily one for the specialist and is continually broadening in its scope. It is one of which the industrial executive is generally in almost complete ignorance. He is usually resigned to his transportation fate and without a capable traffic manager or adviser, neither knows whether his competitor is paying subnormal rates or whether he is paying inflated rates; nor whether, because of these revolutionary changes which our freight-rate structure is now undergoing, both he and his competitor will be paying different rates within a few months time.

Omitting the detail work which does not require unusual qualifications, the principal functions of a traffic department are the following:

1. Watching proposed changes in rates or anticipated changes due to decisions of the Interstate Commerce Commission, or the enactment of new or revised statutes.
2. Analyzing the rates and charges now being paid and negotiating for possible adjustments.
3. Surveying transportation methods, including packing and loading costs and highway, water, and rail rates and service.
4. Handling litigation before the Interstate Commerce Commission and state commissions or determining whether litigation is advisable.
5. Serving in an advisory capacity on matters of plant location, plant enlargements, sales and purchasing contracts.

Department Equipment. Regardless of the qualifications of its personnel, a traffic department cannot function efficiently without the necessary equip-

ment. It must have a complete, up-to-date library of federal and state transportation laws and the reports of the Interstate Commerce Commission as well as indices and digests thereof. It must maintain and keep up to date a complete file of freight rate schedules and must subscribe to such publications as will enable it to keep fully informed respecting our ever changing freight rate structure and transportation conditions. Since an important, if not the principal, function of the traffic manager is to keep himself fully informed, it is also deemed necessary to have memberships in various traffic organizations such as the National Industrial Traffic League and local or sectional cooperative traffic associations.

A traffic manager, just as a carpenter or a dentist, must have his working "tools." Without them expenditures for salaries and office space is very largely wasted.

Selecting a Traffic Manager. The proper functioning of a department depends almost entirely upon its manager. This is true in the case of a traffic department in a greater degree than would be in the case of other departments because not only is his work of a highly specialized nature but he alone knows whether or not the department is functioning efficiently. The greater part, or at least the more important part, of the traffic department's work is initiated and created by the traffic manager.

In a recent publication of the United States Department of Commerce entitled "Industrial Traffic Management—A Survey of its Relation to Business," the following statement is made:

The most important problem faced by an industry in connection with its traffic management has to do with the selection of the staff to be placed in charge. Great care is required in choosing a traffic manager. Few standards for measuring the relative efficiency of applicants are available today. Coupled with this is the fact that the executives who must do the selecting may have a limited idea of the nature of the work that is to be handled.

The Secretary of Commerce in his annual report for the fiscal year ended June 30, 1928, made the following statement in connection with industrial traffic management:

It is further evident that at the present time it is difficult for an executive to determine the fitness of an applicant for such work or to check the capability of the employee after engagement. It is therefore hoped that some system may be worked out whereby traffic clubs or similar organizations may hold public examinations in traffic management and issue certificates of fitness for various grades—as, for instance, director of traffic, senior traffic manager, junior traffic manager, traffic clerk, etc.

A few years, or even a great many years, experience in transportation work does not itself qualify a man as a traffic manager. Industrial traffic management embraces transportation in practically all of its phases, while many men, particularly those employed by the railroads, even though they have devoted many years to transportation work have never had an opportunity to get the necessary experience in the particular branch of traffic work which may be of the most importance to the industrial firm. Since it is often very difficult to find a man experienced in all phases of industrial traffic work, the employer should be careful to see that the man selected is experienced in

freight-rate construction, adjustment, and litigation. This is the one particular phase of traffic work in which experience and study is essential. The novice, regardless of his education and inherent intelligence, is helpless in work of this nature, although he may acquire very quickly a working knowledge of other departmental duties. A good rate man, not one who can merely quote rates, but one who understands the construction and adjustment of rates, must necessarily have a good knowledge of transportation work of all kinds because this is a prerequisite to such rate knowledge. Therefore, to have a good rate man, means that you have at the same time a well-rounded-out traffic manager.

Executives should beware of the traffic manager who appears to be particularly adept at getting last-minute sleeping-car accommodations and who delights in introducing them to high railroad officials. These are no criteria of a traffic manager's ability to do important things, but, on the other hand are usually an indication of his weakness, since they are resorted to as a substitute for initiative and for constructive, valuable work as a means for justifying his continued employment. The executive should not be deceived by unusual energy and interest displayed by the traffic manager when he handles something emanating from his superior executives. This is a most common symptom of weakness. One should remember also that the traffic manager should be the "watch dog" of the transportation situation, that he should initiate and create the work which makes him a well paid specialist and that the handling of the comparatively few matters given him by the executive is actually a small part of his work.

The importance of selecting as traffic manager a man of high character and unusual energy is apparent. He should be a man to whom the work is fascinating and who performs his important duties, not alone for his salary, but for the pleasure he finds in it. Unlike the heads of other departments, he has practically no check on his work and must be relied on both to know his job and to perform his duties in a thoroughly conscientious manner. An industrial executive should not rely entirely on his own impression of a man in selecting his traffic manager nor in appraising his work, but should seek the advice and recommendations of those who are in a position to know properly qualified men.

Outside Traffic Service. Small firms, which cannot afford to pay the salaries commanded by fully qualified traffic managers and to properly equip their offices, should have the services of a traffic consultant. This profession has developed rapidly in recent years and well-qualified, thoroughly reliable consultants are now found in most of the large cities. Most of those of the more dependable type have formed the Industrial Traffic Counselors' Association and membership in this organization as a general proposition gives assurance of reliability and efficiency.

Many of these consultants specialize in rendering a complete traffic service on a monthly retainer or salary basis. These consultants, or at least the more successful ones, have superior qualifications and must of necessity maintain complete equipment such as tariff files and library. Their service is generally more efficient and of greater value than that of a poorly equipped or inefficiently managed traffic department. Naturally, considering the

incidental expenses connected with the maintenance of a firm's own traffic department, the cost of such outside traffic service is comparatively low.

In some cases a consultant is employed on a retainer as an adjunct to the traffic department. This is done where the volume of detail work is so great that the constant attention of a man within the firm's organization is required, but the traffic manager is paid a nominal salary and is not given the necessary expensive equipment. This is practiced by several very large corporations and has been found satisfactory and economical.

Other large industrial firms are having their traffic organization and its work surveyed and reported on periodically by a traffic consultant. This does not necessarily imply a lack of confidence in the traffic manager, but gives assurance that advantage is being taken by every opportunity for savings or improvements in transportation costs and service.

BUSINESS LIBRARIES

BY FLORENCE A. GRANT, *Librarian, Standard Brands, Inc.*

Why Have a Library? The fact that there are today hundreds of libraries established in connection with industrial and commercial firms is evidence that their value is being recognized to an increasing degree.

Modern business calls to its aid every variety of expert and profession, the lawyer, the artist, the scientist, the physician, the teacher and now the librarian. The librarians themselves in the past decade have been gradually adapting their professional knowledge and developing specialists for the business field. New uses for the library in business are continually being discovered, so that it is no longer merely a convenient collection of books where the staff may go to look up the spelling of a word, a date, or the population of Hawaii. It is an active working tool serving every department of the business and every member of the personnel. To stress here only two important "whys," the library is a very effective *time-and labor-saving device*. A private secretary or department assistant need no longer spend hours, often in vain, in a search for some elusive piece of needed information. It will probably be in the library, or if not, the librarian will know where to get it quickly. This brings out the second point. The *librarian can tap many outside sources of information* of which the average business staff is not even aware. The cornerstone of a librarian's training is knowledge of sources of information.

Establishing a Library. There are seven steps to be considered in establishing a library in a business. These seven points can equally well be used as points of departure for a *survey of an existing library*.

1. Why have a library?
2. What kind is needed?
3. Who shall have charge of it? Where does it belong in the organization chart?
4. How shall a staff be selected and where can it be obtained?
5. Where shall the library be located and how equipped?
6. What can be expected of it?
7. How much will it cost?

Types of Libraries. Business libraries fall generally into four groups. In order of their usefulness and also, roughly, in order of their historical development, these are the repository, the research or departmental, the recreational, and the general service types.

The Repository Library. Fortunately, the pure repository type is fast being replaced or expanded into the second or fourth type. It usually began because somebody said, "I haven't room for all these books in my office. Why don't we collect everybody's books and start a library?" Or, sometimes it was started because a place was needed to keep a file of the company's own publications and relics of company history. In many such cases, the custodian chosen was not a trained librarian, therefore it did not grow and develop. Preservation and storage, while important, are far from being the vital functions of a library.

The Research or Departmental Library. The departmental library is established to serve a specific department and limited in scope to the needs of that department. Perhaps most often this is connected with the so-called research or statistical department, but many large firms have an accounting library, a legal library, a technical library, or all of these and several other varieties. When a departmental library has expanded beyond the limits of a small individual collection of books, usually a trained librarian is employed.

The Recreational Library. The recreational library is in one sense a departmental type for it is usually instigated by the welfare or personnel management department and operated by them. But because its point of view and scope is not directed at the subject matter of the business itself, it is classed separately here. Such a library may be purely recreational, including fiction and popular books and magazines, or it may aim to stimulate self-education and include textbooks, vocational guidance material, and opportunity for acquiring a basic knowledge of the business or industry in which the firm is engaged. It may serve only the home office or it may carry on extension work and give service to scattered branches of the company throughout the world.

The General Service Library. The most modern development for the business world of today combines all three of the others. This is the general library or a general library system covering the entire field of the firm's business, used by all departments and managed by a specially trained business librarian. Often several departmental libraries which have developed separately, can be combined in a central location, with a corresponding saving in space and staff, and, if carefully planned, with no actual loss in efficient service.

Sometimes the problem is one of coordinating without combining an already existing group of departmental libraries into a unified system under one control, just as most businesses of today have established central control over purchases, departmental files, and other work of a functional nature.

On the other hand, it is occasionally wise to break down a very large central library into several units in different locations, for the sake of convenience of access, and to obtain more intimate knowledge and attention on the part of the library staff to the needs of some individual departments. When this is done it is important to retain a unified control and a high degree of coordination and cooperation between the separate units. The advantages

are obvious and are the same in principle as apply to any problem of organization: centralized purchasing, reduction of number of higher-salaried positions on the staff, complete availability of entire resources to all departments, avoidance of wasteful duplication in material and records, and a unified system of management so that separate units can be set up as needed, or reabsorbed into the general collection with the minimum of disruption.

Place of Library in Organization. When libraries first came into the business world, their function was so little understood and perhaps so little valued that they were seldom fitted neatly into the company organization. More often than not the library was merely a sort of appendage to the department of the executive, no matter which one, who had been personally instrumental in starting it.

Today the library is as carefully placed and coordinated on the organization chart as any other department. With few exceptions the general library is found in one of three places: as a service department under the office manager, as a branch of the research department, or operating as a separate unit responsible directly to an executive officer.

The first plan is seldom satisfactory. The library is a service department, but it should hardly be classed with the mail or multigraph department, or other obvious sections of the office services. The efficiency of its service is not a matter of office mechanics, but of policy development and cooperation with and from every other department.

By far the largest proportion of general libraries will be found as units of research departments. This is entirely natural since the research workers entering the field of business were the first to demand library service, and the departmental library organized for their use remained under their jurisdiction even after it had expanded to serve the entire business. The only danger in this arrangement is that other departments will not make as full use of the service as they might because they regard the library as the private preserve of the research department, which sometimes has little active contact with other departments. But this is readily overcome by a hospitable attitude on the part of the research department head, by a librarian who watches for opportunities to widen the service, and by a little advertising of the library facilities.

The third arrangement, that of a library operating directly under an executive officer, is followed in some companies with great success, if the officer, usually a vice president, is interested and appreciates the possibilities. This places the library on a par with other expert services, the legal or accounting departments, or the research department itself. The great advantage of this plan is that it is the most likely to insure a rounded development correlated in every respect to the expansion of the business. This is the only practicable type of control where a system of several libraries operates under a central or head librarian. Here responsibility must head up to a point above all departments.

Selection of Library Staff. The first criterion is that this is an expert's job and can only be done by an expert. The librarian must be a trained person, not just anyone who knows and likes books. The second essential is actual experience in the business world.

Sometimes this almost seems the more important. This experience may have been in some kind of commercial, industrial or financial library, or it may have been experience in some other business position than librarian, such as secretary. In other words, the ideal business librarian has been trained as a general practitioner, then has practiced to become a specialist. The lack of this special business knowledge on the part of a librarian has sometimes unfortunately resulted in completely discrediting the library idea with the executives of a firm.

Library schools have of late years recognized this need for specialization and some of them, particularly the New York State Library School at Columbia University, have arranged special courses for those students intending to enter the business field.

The selection of the assistants should be left to the librarian. The positions of stenographer, typist, mail clerk and office boy found in large libraries can, however, be filled through the office manager or the established employment channel, or these positions can be filled by inexperienced library assistants and thus used as training ground.

In establishing a new library, assistance in finding a librarian may be obtained through the library schools, the library associations, the American Library Association and the Special Libraries Association, through employment agencies specializing in this field, and from the local public library, particularly if it operates a business branch, as more than a hundred cities now do.

Location and Equipment. The librarian on the spot is the best consultant on location and equipment. The important points to consider are quiet location for purposes of study, not next door to the bookkeeping machines, convenience of access for the departments using it most, and the largest amount of daylight available, with the best lighting equipment, for the work space. This is more important even than for executive offices, for the library staff are using their eyes continually for at least 80 per cent of the working day.

Some allowance for storage space quickly becomes essential. Much of the material which must be kept in the library does not need to be instantly accessible and can be more economically packed in a closet or storeroom without regard for appearances.

The furniture should be standard library equipment which is specialized for its own needs. Makeshifts do not pay. Open shelves, either steel or wood, are more practicable than closed cases for general purposes, in spite of the cost of keeping the books clean. Filing cabinets may be either steel or wood, but should have well-balanced drawers that handle easily when loaded. In most cases, unless space is at a great premium, legal size files are best. Much of the material to be filed will be larger than letter size, and folding doubles the bulk and is destructive of material. The choice of folders for the files is important. Heavy pressboard folders cost more and occupy more space, but stand up better under hard usage in a permanent file. Light folders have to be frequently replaced, adding to the labor cost.

Other special furniture will be needed—catalogue cabinets, dictionary stands, magazine and newspaper racks and covers, and reading tables. If there are

large charts, maps, or books to be kept, provision must be made for this in special cabinets, shelves, or map cases.

Typewriters may or may not be noiseless, but they must be specially adapted for writing cards. Even standard machines differ very much in this respect, and the library should be allowed to use any special attachments which may help. Certain special library forms and supplies will be needed which cannot be purchased through general stationers.

Work of the Library. The general business library has three major functions: the location of sources and collection of material and facts relating to every angle of the firm's business, the dissemination of this material when needed or when timely to departments interested, and the repository or preservation function.

The last is the simplest to perform. The chief difficulty here is the judicial elimination of obsolete material to keep within the space allotted. Here belongs the work of keeping a record of company history. It must be condensed into compact summary form, but should include usually a complete file of all advertising and other publications of the company. One point should be emphasized here. In a large firm the librarian can scarcely find time to collect this personally. All departments must be required to cooperate and be responsible for supplying facts and copies of publications promptly to the library. However, the library is not the place to store bulky records such as sales statistics, belonging definitely to a specific department.

The second function, *dissemination of material*, is often the point where the librarian has the best opportunity to exercise skill and ingenuity. The best of libraries is useless unless kept in circulation. This is accomplished in various ways:

1. Furnishing specific material on request.
2. Regular routing of periodicals and bulletins to departments interested.
3. Library bulletins, which may be typed, mimeographed, or even printed, and which will include announcements of new material, news items, and reviews or abstracts of important books or articles.
4. Current magazine and newspaper clipping service on requested subjects for individuals or departments.
5. Special services furnished regularly, such as current price lists, coming conventions, lists of ship sailings, etc.

But both material and method must be carefully adapted to the need to be served, if the library is to work efficiently, and a great deal of cooperation is needed from those using it. Persons must return material promptly and should at once stop special reports or items being sent them regularly when the need for them is over. One of the most frequent and exasperating causes of lost time in the library is the client who makes a dark secret of just what he does want. He asks for a specific book, which is sent him, only to find that he wants a ten-place logarithm table, while the book he asked for has a five-place table. If he had been definite in his request the first time, the librarian could have sent what was needed at once.

In most libraries the function absorbing the largest amount of staff time is the *collecting and preparation of material*. This includes ordering and cataloguing books; reading, clipping, indexing, and making abstracts from

newspapers and magazines; the perusal of many catalogues and check lists watching for new material; and the searching of outside sources such as other libraries. This necessarily consumes a tremendous amount of time, because an enormous amount of chaff must be sifted to get at the grain. This is especially true of current periodical material, which must be looked over at once while of current value. The alert librarian is constantly trying to reduce this, and find short cuts such as indexes and digests. The price of such aids often seems very high, but they soon pay for themselves.

The value of any collection depends on its availability, in other words, on the *indexing and analyzing done by the staff*. The small library is no exception. In fact, it is even more important when the material is limited to analyze it carefully in order to use it to the fullest degree.

In collecting material the librarian needs cooperation. Executives and department heads should take the library into their confidence as far ahead as possible. Most business librarians will agree that one of their major needs is establishing "listening posts" in the organization so they may be warned in time to prepare for special demands to be made upon them.

At this point attention might be called to a frequently neglected source of information for the library, the *company's correspondence*. By a little cooperation between the filing departments and the library, correspondence of certain specified types, or with enclosures of printed matter, can be routed to the library before filing. The librarian can glean from this and store away much material, advance information, facts not accessible from any other source, which would otherwise be buried or be lost when the correspondence was discarded as obsolete.

There are certain other routine tasks which may well be handled by the library. Book and magazine orders for departments and even for branch offices will receive expert handling here, and most purchasing departments are glad to be relieved of this work which requires some special knowledge. If the firm does not use an advertising agency, or has not a separate checking department, the records of advertising insertion can readily be kept in the library and invoices checked. In this case all checking copies should be addressed to the library and routed from there after checking to the advertising or other departments who may use them.

Two points on which a definite policy must early be decided upon by the person ultimately responsible for the library, are the question of *personal work for members of the company staff* and *work for outsiders*. The library is a service department and the staff should not be put in the position of refusing service on their own initiative. There must be a settled policy to fall back on, either full service, complete refusal, or a compromise, such as service up to a specified time requirement limit, or service when request is approved by the responsible executive.

The above paragraphs cover the main duties usually assigned to the business library. It is important to remember one thing that the librarian's job, by training and by job analysis, is primarily the *location and rating of sources*, and the *collection of facts*. The *true research function, involving also selection and interpretation of the facts, is another matter*. This calls for a greater subject knowledge or greater special knowledge of the firm's business or of

the departmental work than the librarian has opportunity to acquire. It also demands a different training and skill.

The two talents are seldom found in one librarian and both types of work should not be expected. If such work is to be assigned to the library, then a trained research worker must be put on the staff and helped to the necessary special knowledge. One evidence that these two are rare in one person is that when a librarian is discovered with a special aptitude for research, he is often drafted out of the library entirely and into the research department, where his knowledge of sources makes him invaluable.

Cost. Only a few general points will be brought out on costs because obviously it depends on the work to be done and how large a staff is required. The general scale of business library salaries is higher than in public libraries. This is partly because public service is generally low paid, but also because of the premium accruing to specialization. Statistics are difficult to get because business salaries are seldom published. The range for head librarian probably runs from \$2,000 to \$4,500, with an occasional position running much higher, even up to \$8,000. The average will be about \$3,000. Library trained assistants range from \$1,500 to \$3,000. The average for the senior rank such as cataloguers and reference workers, is about \$2,200. The miscellaneous positions would receive the local market rate for stenographer, etc. Salaries will always be the largest item of expense, running from 70 to 80 per cent of the total budget.

The other large item is the material content of the library, and here again only general points can be made. Some libraries will find book expense a much larger item than others. Scientific books and art books are examples of high-priced material; also, scientific books must be soon replaced by new editions or up-to-the-minute works. Some libraries will find their most valuable material in periodicals and trade papers, and this account will be very heavy. It is also heavy in technical libraries because scientific periodicals are many and costly. In this connection it is interesting to note that indexing costs for magazines have recently been worked out. It was found that the salary cost alone ran about \$60 a year for each monthly and about \$260 a year for each weekly.

The Budget. The cost of the library is not always viewed sensibly by executives. It is of course an indirect service whose output cannot be exactly measured or priced. For this reason it is liable to be either starved or spoiled, sometimes alternating between the two. Any business librarian will welcome the introduction of a budget as an evidence that the department will be considered by the management on the same scientific basis as other parts of the business. But the budget should take into consideration the year to come as well as past years, and the librarian must be taken into the confidence of the planning department, and not left wholly to steer the course by straws in the wind. If there is to be any expansion in the business during the year involving increase in general staff, probably a corresponding increase will be needed in the library. If there are to be new departures, new products introduced, provision must be made for extraordinary outlay to cover equipping the library with books and materials covering these subjects, just as the factory will have to be equipped with new tools and machines.

This would seem to be a very good point on which to finish. The library in business needs to be considered in the light of scientific management. It has through the pioneering qualities of its librarians been doing excellent work for many years for the business world. But too often it has not received the needed attention from management to realize its full possibilities. It has been tolerated and pointed to with pride; it has been considered a luxury which followed other luxuries into the discard in periods of economy; and it has been considered a thing apart and left strictly to its own devices.

But through better understanding of each other's jobs between the business man and the librarian, and longer experience in working together, the library is fast being integrated into its place as a valuable tool of business, to be studied, improved, utilized to a larger extent, and accounted for just as any other tool.

MANAGEMENT RESEARCH METHODS AND QUALIFICATIONS¹

BY W. J. DONALD, *Managing Director, American Management Association*

The Engineer in Industry. Twenty years' progress in management owes much to science. Scientific methods of finding the solution of management problems have brought light to many a dark corner or narrow and tortuous alley.

It is easy to understand how scientific method made its first large contributions to the field of production. There the engineer has been a power for decades. For a long time, to be sure, he functioned as an advisor, first largely as a consulting engineer, and later more and more as a full-time member of the staff of a company. Of recent years a rapidly increasing percentage of line executives in factories, railroads and public utilities have been drawn from the engineering profession.

It is popularly believed that electrical engineers are better trained than others for the electrical manufacturing business, for the operation of electrically operated railroads, and for the operation of power plants; that mechanical engineers are better trained for the operation of industries in which machinery plays a large part, and that similarly chemists and civil engineers are especially well equipped for certain classes of production in which their respective types of knowledge are particularly helpful.

While acknowledging the value of a grasp of particular fields of knowledge, many are thoroughly convinced that it is not so much a knowledge of mechanical, electrical, or civil engineering or chemistry which has brought this type of trained man—the engineer—into his own in the production side of industry. Engineers won their present place in corporate organization chiefly because they had acquired a technique of investigation which is essential to modern manufacturing and utility operation. The processes of analysis which are applicable in engineering or in chemistry are fundamentally alike for all. These processes are the discovery and verification of facts, scientific methods of analysis of facts, and the discovery and proving of relations of cause and

¹ Taken by permission from *Harvard Business Review*, pp. 149-156, January, 1927.

effect. The devising of solutions of problems thus analyzed, experimentation with devices to meet the situation under investigation, and the measurement of results of experiment are the closing chapters in the application of those scientific methods which sound engineering training provides.

Not every engineer, so called, has this equipment. It is possible for men to acquire engineering degrees who have no grasp of those research methods without which no education can be said to have provided a scientific equipment. Mere mechanical lore never made a man a scientist. Nor is knowledge of formulas sufficient. In college days many engineering students debate whether it is necessary to learn how a formula is derived or why it is true. Some think it sufficient figuratively to carry the formulas on their cuffs. How far such men get in the practical world depends, of course, on how often they meet recognizable problems for which their ready-made formulas will apply. What they do on meeting new problems would itself make an interesting topic for scientific investigation. Probably most of them sink to the level of skilled workmen or turn their energies into channels where a providence-provided personality makes up for lack of equipment in scientific method.

Scientific Method in Production. Industry today makes vast demands on the man equipped with scientific methods of approach to the solution of problems. There are more variables today in any production situation, and the solution of problems through the isolation of particular factors presents greater difficulty today than ever before. "Hunch" methods of appraising a situation are utterly inadequate for the needs of most companies. It takes more than "common sense" to determine whether the installation of certain conveying machinery combined with an incentive plan complicated by labor organization, may be desirable at present basic wage rates, affected as everything may be by apprentice training, the trend in labor legislation, immigration restriction, the possibilities of increasing foreign markets, the invention of new machinery, the trend in capital costs, and so on, and so on.

And there is more at stake—in dollars, reputations, and human welfare. Even if the largest companies made costly mistakes in the nineties or even later, their bankruptcy did not start even a good-sized ripple, let alone a financial panic or an industrial crisis; but let one of the larger automobile companies design a new model in which there is defect enough to prejudice the buying public and the sequel is a litter of damaged reputations, executive job hunters, uncomfortable visits to the bankers, stormy stockholders' meetings, labor out of work, a heavy turnover of salesmen and agents, and unfavorable budget comparisons for every company that supplies raw materials, parts or accessories, and probably a general disturbance in the price lists of the automotive world.

The purely technical engineering side of production has no longer a monopoly on the need for scientific methods of research. Probably it never did have, but now we know it has not. There is scarcely need to recount relations of cause and effect which bear on the whole situation. While there are companies which are satisfied to apply to labor symptoms a gloved hand where a mailed fist formerly reigned, there are others whose investigations get to the roots of problems and effect changes of policy and practice as regards benefit systems, pensions, wage plans and rates, and everything else affecting

the human factor in production. Some are willing to use selective tests which others in only partially similar situations have used with supposed success. Others devise their own tests for particular circumstances and test their validity against performance. Some companies adopt ready-made wage plans without analysis of their applicability and without measuring their effectiveness, and their executives are loud in their claims of achievement which they might or might not be able to prove. Not infrequently without analysis the same plan is applied to all workers, even though in dissimilar jobs, and to jobs in entirely different lines of industry. Some companies adopt ready-made instructional material for training apprentices without analysis of the job difficulties of the particular industry or company.

In other words, the need for scientific analysis arises from every corner of the whole production problem—management as well as engineering in the limited sense of that much abused term.

Hence it is that the man trained in scientific method has assumed a position of leadership in the whole production world. The really competent production executive today must have such a grasp of management research methods that he can carry on his own investigations, or at least can sufficiently interpret and appraise the soundness of recommendations of his associates.

Management as a Profession. Production management has thus become or at least is becoming a profession in which the man equipped with scientific methods of investigation—usually the engineer or chemist—is in the saddle.

While production has had the bulk of scientific attention, yet problems of marketing, office management, finance, and management organization are being subjected to similar scrutiny. In some quarters scientific methods have been applied to these fields for years or decades. In many quarters production received first attention, and the contagion has spread throughout the company or has been forced on divisions which were otherwise immune.

The engineer, the accountant, the actuary, and the economist are at work in every department of business and every phase of management. To put it in more generic terms, the techniques of the historian and the statistician which are the fundamentals of every scientific investigator have been put to work in the cause of better management. All of management, having thus risen somewhat out of the hunch stage, is thus becoming a profession.

What constitutes a profession? Henry S. Dennison, president of the Dennison Manufacturing Company, and Joseph H. Willits, Professor of Industry, University of Pennsylvania, have drawn up five criteria as follows:

1. A profession is an occupation which requires intellectual training as contrasted with mechanical skill.
2. A profession employs the fruits of science; uses the scientific method and maintains an experimental attitude toward information.
3. The professed knowledge is used by its applicant to the service of others, usually in a manner governed by a code of ethics.
4. The amount of financial return is not the chief measure of success.
5. The professions are given public and often legal recognition.

These criteria are of two types. The last three bear on the professional man's relations with others in the profession, to the client, and to the public.

The first two have to do with his equipment of scientific methods of investigation. Note that it would be hard to write into these criteria any idea that mere knowledge of facts is a part of professional equipment. Rather it is "the use of scientific method," and the "experimental attitude toward information" which are emphasized. Intellectual training consists of the attainment of these—not the mere acquisition of information.

Technique Rather Than Information. Valuable as information may be, its acquisition does not constitute scientific training or make a man a scientist.

This leads to the most important part of collegiate training in management. It has not been unusual for even some of our best known professors of management to emphasize subject matter to be covered and the sequence of courses—the main idea being the acquisition of knowledge about business management or information about management methods. Too often there is no evidence of an understanding of the true purpose of education—intellectual training in the sense of a technique of investigation.

The amount of information about management which college students will obtain in a two- three- or four-year course is relatively unimportant compared with what will be acquired in the first few years of business life. In any case its value is ephemeral, for the methods of management are developing and changing so rapidly that what is known today has become obsolete in a surprisingly short time. Furthermore, the text-book and collateral reading material used in class is too often already several years old. One need only recall the rapid development of budgeting methods or the radical change in attitude toward methods of employee training to illustrate this point.

What is of permanent value to the student is the acquisition of *technique of investigation as applied to management*—the impulse to verify facts, to challenge mere gossip and impressions, the power to use statistical method and to handle historical evidence.

This is the content which is common to the whole field of management—sales, production and finance—and it is from this type of training that management is going to realize its greatest development.

To these ends, the whole university curriculum may contribute. The classics can be defended not so much by the threadbare argument that one may thus acquire a knowledge of the roots of language and an appreciation of the literature of the centuries, as because they contribute to the technique of getting at the truth. The value of mathematics, modern languages, the physical and the social sciences, lies in the same direction. This is what we have sometimes called mental discipline.

Our collegiate schools of business are, of course, nearly all offering courses in statistical method. There is none that is giving specific instruction in the treatment of historical evidence—yet historical evidence is probably even more abused than statistics when applied in the management questions. The study of statistical method is fundamental for the future work of the investigator of management problems. But most of our colleges can go still further. Accounting can be taught universally, as it is being taught in some institutions, not as an equipment for keeping a set of books, but as a technique of management research. Everywhere through instruction in management there should be training through actual practice in the process of

investigation. It is a common complaint that some universities advance their staff members on the basis of the results of their researches. The policy has been criticized on the ground that the professor who is a good teacher is equally as valuable as the good investigator. Many sympathize with this point of view. As a matter of fact, the chief objective of education—intellectual training as we have defined it—cannot be achieved by men who lack the spirit and technique of the scientist, and no one can be a good teacher who cannot and is not demonstrating his ability to do research. Too often what is referred to as good teaching is nothing more than interesting lecturing, combined with a good technique for compelling students to acquire information which they spill out on schedule on the inevitable examination paper.

Probably professorial advancement could be placed on a middle ground by being given to those who, with the spirit of and capacity for research, at the same time are able to and do develop in their students the same spirit and capacity.

Now practice in scientific methods of management research is not to be acquired with entire satisfaction in an artificial or miniature world. It calls for a vast extension of cooperative business research. The faculty and the students must have real problems to investigate if the technique of investigation is to be imparted so successfully that it becomes the permanent equipment of the student. In this extension business executives have their part to play, and they have no real claim to a right to criticize until the way has been made reasonably smooth for our educational institutions.

There is already a vast literature on management, much of which has a great, even though temporary, value. It is growing by leaps and bounds, thanks to the activities of societies and the efforts of the publishers of journals and business books. Let us hope that the process may go on unabated. It serves to meet a pressing need. Executives meet to exchange experiences on management methods (not research methods) used to meet specific problems and share opinions regarding the merits of their methods. Let that, too, continue unabated. The inclination to investigate a company's problems must be preceded by an awareness that problems exist, and the knowledge that other companies use different methods is likely to stir executives into action.

So, too, there are histories and biographies unending, so much so that one almost has to make history in order to find a worthy topic for investigation. But of literature on the treatment of historical evidence and the verification and interpretation of evidence there is a dearth. Management suffers from the same lack.

Need for Scientific Study of Management. A beginning has, of course, been made. Management societies have published a few papers which merit inclusion in a list of documents on management research methods. Despite a comparative lack of appreciation, the publishers have also offered us a few books of similar importance.

There is a considerable number of books on statistical method which are useful to the investigator of management problems, but their value is considerably reduced by the fact that examples of the application of statistical method have little or no relation to management. And as for literature on

methods of treating historical evidence in the field of management—find it if you can.

It is easy to agree that there is ample room for a body of literature of scientific methods of investigating management problems.

What have we a right to expect of the future? There is set down below a few of the topics on which papers of merit would be welcomed by the business world. And for the sake of clarity, there is set off against each, topics which do not belong in the field of research methods. There is a clear line of distinction between management research, management methods, and management research methods. It is the development of the latter and the ever widening number of competent users which will contribute most to the cause of management either as a movement, a body of knowledge, or a profession. Without it there will be a dearth of sound management research and much less than we need of effective management methods.

These documents do not, of course, include numerous papers in which are presented management methods which have been adopted after scientific investigation or conclusions regarding results achieved which are based on careful scientific measurement and appraisal. Such papers are extremely valuable in suggesting lines of investigation for those whose problems have not been satisfactorily solved, but their value presumes that those to whom they open up a line of investigation are equipped to study the problem scientifically, and will not merely adopt a management method ready made without, in addition, ability to measure the results achieved. Unfortunately, this presumption has altogether too little validity.

Some possible topics are as follows:

1. The method of determining what incentive plan would best suit a particular class of employees; *not* the art of installing an incentive plan.
2. The method of measuring the results of the installation of an incentive plan; *not* experience with or the results from installing it.
3. The formula involved in determining what the financial liabilities under a pension will be; *not* the actual financial liabilities under a pension plan or the experience of various companies.
4. The method of determining the best method of posting; *not* the best way to post reports.
5. The method of determining and testing a test for selecting employees; *not* experience with tests for employees.
6. The formula for going about a classification and rating of executives; *not* experience with a plan for classifying and rating executives.
7. The technique of determining where to locate a plant; *not* conclusions as to where to locate a plant.
8. The technique of making a job analysis and of standardizing salaries and wages; *not* a classification of standard jobs and a salary or wage standardization plan.
9. The formulas for significant ratios; *not* actual operating or balance-sheet ratios.
10. The method of determining economical quantities; *not* the economical quantities for production.
11. The method of determining the instructional material needed; *not* the proper instructional material for a company's salesmen.

12. The technique of market analysis; *not* conclusions regarding markets for a commodity.

Other Criteria of a Profession. What can be said of the other three criteria? They have to do with the ethics of a profession. Frankly, the situation looks more than usually complicated, though probably not more so than the circumstances surrounding the birth of the medical, legal, or engineering profession. There are, of course, the relations of the consultant with the client, with his staff, with each other and toward the public—the consumer. Executives of companies who hold advisory positions have delicate problems of relations with outside consultants, with their own subordinates, with line executives high and low, and even their obligations to the public and to their own selves. Line executives who have the spirit of the scientist have their relations with other line executives, with advisors, with their superiors, and with their subordinates, including the workers.

What is the ethical content common to all of these? We find in them only three principles—namely:

1. Allegiance to scientifically determined truth.
2. Willingness to share the knowledge of scientific methods of investigation with others.
3. Willingness to reward with recognition competent users of scientific research methods and especially those who have contributed to the body of knowledge of management research methods.

Nothing else will develop allegiance to scientifically determined truth as will following the road down which it leads. It pays in satisfaction and in dollars. At least a considerable number of us will agree, without argument, that it does. One can lecture by the hour about the value of civic pride or civic cooperation, but none will be forthcoming until citizens get into action for the town. Moralizing about loyalty to truth will make no impression until it is practiced. Then it will need no argument or moralizing because it will have become a habit of mind.

There are still many companies which will not share their experience with others, especially competitors. By and large, they are taking a short-sighted view of matters. A competitor is never so dangerous as when he is incompetent, and especially when he does not know the facts of his company, his line of business, and business conditions generally. The company which accepts the salesman's alibis for not bringing in the orders—especially the statement that competitors are cutting prices when they are not—or which cut prices because it does not know through its trade association that it is getting its share of a depressed market, is a menace to the trade.

There is only one limitation to indiscriminate willingness to share experience with others. It lies in the danger that inadequately trained men will apply management methods to situations which they do not fit. Sharing experience with them is as likely to lead them astray as to help them. The remedy, however, lies not in secrecy but in the spread of an appreciation and knowledge of management research methods, with the aid of which a company's own problems may undergo thorough investigation along channels suggested by the experience of others. In the sharing of knowledge of the technique of management research there need be no reservations.

Indeed, this much at least is a professional obligation. In medicine, it has been a point of professional honor that all discoveries shall be shared; whoever exploits a discovery is considered a quack. Secrecy about management methods has gone out of style, and unwillingness to discuss methods with others is mostly due today to lack of confidence that the right thing has been done or to lack of time to prepare adequately a satisfactory presentation. Executives who are sure of their accomplishments are extraordinarily willing to talk about their achievements.

CHAPTER V

EXECUTIVE PERSONNEL PROBLEMS

THE DISCOVERY OF EXECUTIVE TALENT

BY W. W. CHARTERS, *Director, Bureau of Educational Research, College of Education, Ohio State University*

The scarcity of executive material is due in large measure to mismanagement. It belongs on the same low level of planning as entering the Christmas season without an adequate stock, meeting sowing time without seed or equipment, reaching old age without enough money to support oneself, commencing construction without materials, and starting an expansion program without arranging for the necessary capital.

When management prepares for executive vacancies with the same resourcefulness that it now uses in planning for production, purchasing, accounting, and financing, the supply of good executive material will exceed the demand.

Relatively Small Number Needed. The problem is not a serious one to solve. Grant, as we may conservatively do, that executive positions in an organization are one-tenth of the total force and that the executive turnover is 20 per cent and the employee turnover 100 per cent, only two persons to every one hundred persons employed each year are needed on the average to fill the vacancies. No employment officer of average capacity will have any difficulty in employing two or even four or five people per hundred who have possibilities for promotion. There is enough raw material entering every year into any organization, where intelligent selection methods and long time planning are used, to swamp the demand for executive positions.

The task of filling executive positions is so much the easier because not all executives need to be Henry Fords. In every organization the majority of executive positions, those of a minor sort, are relatively routine jobs whose mechanical aspects can be quickly mastered and whose personnel duties consist of keeping subordinates busy, happy, and efficient in the performance of simple routine duties. It is both impossible and fatal to fill these positions permanently with people of unusual ability. It is impossible because they will not stick; it is fatal because it destroys morale.

Vacancies in the major positions which demand more than these simple essentials of character and leadership are much fewer in number than two per hundred per year, perhaps one in five hundred. To fill these in an organization of 3,000, the employment office and other selecting agencies would have to provide six people net each year who would at the proper time in the future be ready for major positions.

Theoretically, this again is a simple task. The scarcity is not in the raw material. It can be secured. The weakness lies rather in what is done with the people after they are employed. Ordinarily, at the present time, these undiscovered future executives are put to work on assigned jobs and are told more or less efficiently how to perform the duties for which they have been employed. But there is no plan for spotting them or for giving them special attention when discovered. By a process of what is essentially hit and miss self-education, some of them may stand out as better than others to the extent that they will attract the attention of somebody and in due time be mentioned in connection with promotional vacancies.

The "Can't Keep a Good Man Down" Theory. This is the ordinary planless method of selecting and training executives which with a few improvements is typical of this era of American business life. We believe the foolish theory, variously stated, that cream rises to the top, that water finds its own level, and that you can't keep a good man down. It is true, of course, that cream does rise to the top and that water seeks its own level, but cream is cream and water is water. Neither cream nor water is human.

The statement that you can't keep a good man down is careless bunkum invented by men who have risen to the top to explain why they have risen. Thousands of good men have been kept down by adverse conditions who would have risen had conditions been different. The raw material was good, but the retarded executives were kept down by blind-alley jobs, by belonging to a poor company, by careless bosses who did not know how to develop them, by hard luck, or by the lack of some quality that was essential in one organization but not of equal value in another. There are many good men, as far as native endowment is concerned, who have never risen and reached the top. I venture to assert, after some years of observation, that in any organization which I know a different president would have selected different executives from among the same employees and have had executives which were equally good as those now in control. Accident and environment play too large a part in selection to leave any foundation for the theory that you can't keep a good man down.

This hit-and-miss method of discovering executive talent is so unsatisfactory that business is becoming vocal about it. The subject of poor executive material is a favorite topic of discussion whenever major executives foregather. Undoubtedly, the supply of well-trained executive material is running far behind the demand. It could not be otherwise when so little attention is paid to its selection and training. While American methods of production, distribution, and financing have reached a position of international prestige, executive training is still in the primitive state where medicine was fifty years or more ago. Little use is being made of the enormous advances in science, psychology, and the art of teaching. The same hit-or-miss methods which have always held still prevail.

Yet, while this is, I believe, an accurate description of the conditions in the majority of organizations, a handful of men have been struggling with the problem in their own particular organizations and have reached conclusions here and there which possess enough validity to be useful as suggestions. These it has been our good fortune to examine, some by personal contact, and

the remainder by extended correspondence with fifty progressive firms through the courtesy of the American Management Association.

In this paper we shall deal with the topic of the *discovery* of executive talent, and in a succeeding report we shall present programs for the *training* of junior executives. For purposes of clarity and for convenience in discussion, I shall present a program for the discovery of executive talent in the form of a series of recommendations, as follows:

Program for the Discovery of Executive Talent. 1. *The attitude of the president, vice-president, and managers of an organization must be entirely sympathetic to executive training*, and this sympathy must be exhibited not only in feeling and conversation but particularly in *active cooperation*. If the major personality in an organization is not completely interested, it is a waste of time to undertake the project. If, specifically, he fails ordinarily to handle his own people in a manner that is an example to his subordinates, any program will result in failure. Machines and systems of accounting may be bought to do mechanical work, but the training of people cannot be handled by the adoption of resolutions or the issuing of commands. Personality must touch personality beneficently. A father may hire tutors to rear his son, but if he himself does not take a hand in the education, the boy loses something. Materials may be bought with money; training comes through personal contacts. Nothing can be substituted for this. Major executives can be exhibiting outbursts of anger and by habitual bad handling of people completely destroy the efficiency of a peerless training system. If one were approached to install a program of executive training, the first persons to size up before accepting the assignment would be the president and his important executives. If they do not possess the desire to be good trainers of their own immediate subordinates, a wise man would refuse the assignment because he knows that he would fail.

2. *One executive trainer* should be appointed. He should be a *major* executive with responsibility for the selection and training of executives. This is necessary for two reasons. First, the planning involved in the filling of vacancies is so important that responsibility should be placed in the hands of a single competent person. Second, no person can handle the training of executives who does not have the prestige that comes with a position and salary that is considered important in the organization.

This responsibility is both direct and delegated. Some of the work he must do himself; most of it, however, he delegates to line executives and others and sees that it is done. For in the last analysis each executive is responsible for training in his departments; that is one of his functions. But wise management details to one person the responsibility of seeing that executives perform their training duties efficiently.

The executive trainer exhibits a number of specific qualities. He is a good judge of men; he is forceful in personality; he loves the job of developing people; he is sympathetic; and preferably he has had teaching experience.

Whether the executive should give his whole time to the problem depends upon the size of the organization. In an organization of 1,500 employees, he will be kept fully occupied. In a smaller organization other duties may appropriately be performed by this executive.

3. A general policy of *promotion from within the organization* should be adopted. To this recommendation there are two sides. Appointment from the outside is good when the new man brings new ideas, and it is necessary when an organization has gone to seed to such an extent that new ideas cannot be found within the organization. There is a danger that promotion from within may thus lead to inbreeding. Yet, in an active organization there are so many sources from which to gather new ideas that it is not necessary to employ executives from the outside merely to learn from them: consultants can be engaged, and executives can read, visit, and interview. Only in special cases is it necessary to bring in an outsider. This may be necessary in the employment of technical executives such as lawyers, doctors, engineers, and the like. In these technical positions, where only one expert is needed to supervise the work of untechnical clerks, it would be a waste of money to provide an understudy merely for the purpose of having somebody ready if and when the executive happens to leave. In other cases outside employment is necessary when the management is caught unprepared to meet a vacancy through accident or carelessness in not having provided key men who can fill the position.

But this is always at the expense of morale. The juniors in the organization who see foreigners selected with great frequency either grow disgruntled, lose ambition, or leave. No young man will give his best to an organization in which he is likely to be debarred from the prize positions that are always, or frequently, awarded to outsiders.

When, therefore, new executives are brought into an organization, care is taken (in all of the fifty organizations that cooperated with us in our investigation) to preserve morale by taking into confidence those within the organization who might consider themselves to be candidates for the position. Our firms tell us that management should be able to make a good case for such appointments by showing that the position requires unusual technical training, that the outsider has outstanding qualifications, or that the reasons for the action are exceptional.

Management should be completely sold to the idea of promotion from within to the point of being quite fussy about it. The opposite policy is like the hand of death on the initiative of employees and assistants. An organization that is committed to outside selection as a major policy can never have superior under executives. They will become mere job holders, not because they lack natural ability, but because ambition is killed.

4. A *personnel inventory of all executives* should be installed. This inventory includes the following three major items in addition to other minor or special items: (a) ability to produce results, such as, profits or output in the department; (b) ability to train his people, as well as to maintain their morale; (c) evidence of growth as shown in installing new ideas in his department and in suggesting new ideas both for his department or for the organization as a whole when he does not have control of installation. Evidence on these points should be secured from line executives superior to the executive being inventoried, and the judgment of as many such executives as possible should be secured.

The importance of records cannot be over stressed. No executive (or group of executives) is able to keep in his head either the names of all prospects or complete information about any one prospect. The comptroller keeps financial records because he must have exact information. The personnel officers must likewise keep personnel records if their information is to be equally exact.

5. *Annual inventory conferences* are held. At an appropriate time, and at least annually, the president calls for these judgments and holds conferences with his major executives to take stock of the executive personnel. At such conferences, the executives may be classified into four groups: (a) those whose work is satisfactory; (b) those who are not satisfactory but may improve with training and stimulation; (c) those ready for release, promotion, dismissal, transfer, or retirement; (d) those who as far as can be learned are likely to leave voluntarily.

From such a conference, which of necessity must be an extended meeting or series of meetings because of the importance and complexity of the subject, the executive trainer will be able to work out a program. He will know approximately the number and kind of positions to be shortly filled and will be prepared to bring to the attention of those concerned the prospects who may be considered in filling the positions. In an ideal situation, he will have someone on hand ready for each position. In a practical situation he will usually need time to get ready for the filling of vacancies.

Such a detailed forecast of just what the demand for executives will be in an organization is absolutely essential for the operation of any training program for executives. It is important because on the one hand the trainer needs to know approximately how many will be needed so that he will not be caught short. On the other hand, he must avoid the deadly pitfall of preparing more people than there are positions to fill.

6. As a result of formal conferences such as those mentioned in the fifth recommendation and of informal conferences with the president or other major executives, the executive trainer will formulate the *type of qualifications that make for success in his organization*. This is necessary because undoubtedly executive qualifications that are essential in one organization may be detrimental in another. To illustrate: In organization *A* the executive must be able to "stand the gaff" and fight back in family rows; but in organization *B* criticisms and reprimands are much less frequent or more subtle. In organization *A*, a sensitive man would be a ruined misfit, even though he had superior ability; while in organization *B* he might blossom into a powerful personality. Converse, the aggressive "scrapper" who would fit into the executive group in *A* might never be more than a crude outsider in *B*.

Organizations have personalities as distinct from each other as those of individuals, and the executive trainer must have a clear picture of the type to which he has to build. He must pick people who will fit. Not for him is the task of radically changing this type, unless a new management with different qualities has recently been installed. The executive trainer must not develop people who merely suit him personally; he must select individuals who fit into the organization family.

Not only does this hold for major executives, but the trainer must also have clearly in mind complementary personalities in lower positions. If a section manager is in need of an assistant, the selection of this person will depend upon how well he fits in with the manager, partly to be congenial to him and partly to supplement the points in which the manager is weak.

In brief, efficiency of selection demands a knowledge of the subtle personal qualities which will make for success in each organization and in each specific situation within the organization.

In general, however, there are five *basic qualities* which are essential in good executives in all positions. To me, the following are the major qualities:

- a. Forcefulness enough to put across ideas which we believe to be right and persistence enough to stay with an idea until it is used.
- b. Dependability in performing well those tasks for which we are responsible.
- c. Criticalness which enables us to see those things that are not right.
- d. Constructiveness in suggesting practical methods for improving the things we criticize.
- e. Kindliness of spirit as a background of all our contacts with people.

A good executive is critical of everything that is done, including his own actions and convictions; he is able in the end to accompany a criticism with a method of improvement; he has the personal force, clarity, convincingness, and "guts" to put his suggestions across; he can be counted upon to fulfill his responsibilities with care; and behind his actions, he thinks kindly of people and is quick to see the good in them, the more so because he must be critical of everything and everybody. These are the elements of growth. When the executive ceases to grow, he dies.

7. All the major executives are stimulated to make a hobby of *discovering undiscovered talent*. This is difficult because when the executive makes his rounds and comes into contact with his people there are problems on his mind. He is then chiefly concerned in locating trouble and placing responsibility for mistakes. Consequently, he is not in the mood on such occasions to look for bright people, nor to recognize them; he can hardly keep from feeling that they are all dull. Therefore, he may need reeducation if he is to become interested in recognizing in some of the delinquents those abilities which when properly trained may develop into good executive material. For, if someone does not discover those who, with all their faults, are still capable, the management cannot hope to supply the executive demand. Clearly, on the executive trainer rests the responsibility for this reeducation.

8. Machinery should be set up in the office of the executive trainer for assembling *data on all likely prospects*. Here, on individual forms will be found names, histories, production records, and records of opinions concerning every individual in the organization who is thought to have executive possibilities.

9. The process of selection should begin at the door of the employment office when the rank and file of employees are engaged. Increasing attention is being given in many organizations to recruits from colleges and professional

schools. Just why the college man is supposed to be better than other men, I do not know. I think that it is chiefly due to the fact that he sees more broadly because he has read more widely. There is the further fact that he has more confidence in himself because of his college education in comparison with the young man who has not gone to college and feels that he has missed something. Certainly in many of our companies the trend is strongly set toward recruiting college graduates, and this is clearly wise where technical information is an essential qualification for an executive position, as in engineering, for instance. Some organizations make yearly visits to schools in the spring of each year. Others make college contacts through former graduates now in their employ, and still others through personal acquaintance with professors. Much of this recruiting is done merely to fill positions where no immediate thought is given to the later filling of executive positions. In several organizations and particularly in the department stores, college men are secured avowedly for the purpose of filling executive positions after training and are put into classes where the period of apprenticeship is short-circuited from the usual period of several years to from six months to two years. What the results are on morale and how effective the plan will be is not yet clearly demonstrated. So far as I can learn, those organizations that have tried the plan still believe it to be efficient.

In selecting college men the personal interview draws to focus scholastic standing, the judgment of the institutional employment officer, and of instructors, and evidence of extracurricular activities such as athletics and fraternity affiliations. From all these sources data are collected as to the personality, mental ability, and reliability of the applicant.

Few of the organizations normally select employees by approaching those belonging to other organizations. It seems to be a clause in the unwritten code of business ethics that the employee who wishes to change must apply. Little use is made of commercial employment agencies, but selection from among friends and acquaintances of present employees is very common and is highly considered. To a greater extent in looking for promotional executive material, the friends and acquaintances of executives are considered. This is due to the fact that such individuals may have an initial personal interest and will be likely to fit in if they show executive ability. But in all the cases reported, these persons are treated as though without influence, and undoubtedly in efficient organizations this is a fact and not a gesture. For nothing is more fatal to an organization from the point of view either of morale or efficiency than for the desirable promotions to be secured by friends of the management who have not merited the advancement. Normally, therefore, in our companies, the future executives enter through the employment office, not as potential executive timber, but as workers in the ranks employed to perform the duties for which they are engaged.

10. In securing executive prospects within the organization *informal* quests for material by the executive trainer and informal reports by individual executives to the executive trainer are supplemented by a formal request made at stated intervals of all the executives who collectively know the rank and file of employees. This request asks for the *names of additional prospects who have recently attracted attention*. The employment officers usually

provide the largest number of names. Particularly useful in selective sifting are the names of those employees who interview the employment officers seeking for raises in salary, for transfers, or for advice about their prospects of advancement. In this group are frequently found people of superior ability who are genuinely interested in advancement and have reached a point where they are considering a change of employment. To these names provided by the employment officers are added, by line executives, names from their own department and from other departments with which they are in touch. Staff executives and the executive trainer supplement these nominations from other sources.

11. The executive trainer sifts these prospects by the application of a variety of methods as follows:

a. He uses *intelligence tests* as a matter of routine procedure. Selecting any one of a number of good general intelligence tests, he standardizes it for his organization by giving it to the present occupants of executive positions to discover the maximum and minimum, the median and quartile grades for each group. For instance, in a department store, he sets up the scores of the major executives as one group, the buyer as a second, the assistant buyers as a third, and so on. By this means he sees about how much general intelligence is needed to fill each of the positions as well as it is now being filled. In addition he is able to determine upper and lower critical scores. If he finds on a scale of 150 that assistant buyers seldom rank below 70 and seldom run above 120, he would not be justified in giving close attention to a prospect for a position who has a rating either above or below these two points. If below, the question is raised as to whether or not he would have the brightness to fill the position. If above, the question arises as to his being too bright to hold the position for a period long enough to make it worth while to promote him into it.

Obviously, the intelligence score is not a complete measure of probable success. Forcefulness, ambition, likeableness, and other qualities of personality are equally important factors. But other things being equal, bright persons are more successful than dull ones in major positions, and the executive trainer is better able to place his people if he has an index of their mental brightness and has standardized ratings for his organization.

b. He will have *performance records*. In every organization with which I am acquainted, there are a number of records in the files which merely need to be assembled, and to these are added other records which should be kept for the needs of the personnel inventory. A few of the items which can be assembled are: sales percentages (in selling organizations); production records, absences and tardiness; service shopping reports (in department stores); and errors. Not infrequently, a study of these records will reveal unusual persons who have not been reported to the executive trainer by other executives.

c. *Reports from superiors* will be assembled. These take two forms: letter reports and rating scales. When a letter report is used the executive addressed is asked to give in his own words his impression of the strength and weakness of the prospect. When the rating scale is used the points upon which the executive is asked to express his judgment are listed, and he is directed to give a rating in symbols: a numerical rating on a scale of 1 to 10

or a grade by letters as A, B, C, D, E, or grades by points on a horizontal line in the graphic rating scale. When numerical ratings are used some organizations weigh each item and total the score of each individual on a scale of 1 to 100.

Some form of rating scale is used widely by our organizations. The scale has the advantage of compactness and inclusiveness of those items which are considered to be essential. It has, however, two disadvantages. In the first place, because the raters do not use the same basis for judgment, there are wide differences in the judgments upon the same individual. In the second place, it is difficult from the study of scales to get a clear picture of the individual rated. I have a personal preference for the letter type because the rater is left free to hit off the characteristics of the individual in his own words, and often these words are more revealing than the checks or symbols on a rating scale. After I examine a scale I always feel an urge to ask the rater to tell me what he really thinks of the individual. But this may be a personal idiosyncrasy.

When the letter type is used, the opinions should be written on a prepared form for ease in filing and handling, and preferably, the rater should be asked to give his opinion upon certain essential points which are listed in the request form. However, as has been said, he should express his opinion in his own words.

I am strongly inclined to believe that totaling numerical scores in rating scales is statistically inaccurate in view of the fact that the ratings on each point of the scale are so highly subjective. In either case, however, opinions should be collected from all who have acquaintance with the individual.

d. Organizations which give prizes for suggestions for improvement of procedure as in the form of the suggestion box utilize the returns from individuals to spot those who have ideas. They feel with justice that those who are sensitive to problems and resourceful in suggesting improvement possess two basic executive qualities.

e. When employees take courses in formal classes those students who rank high in scholarship or show forcefulness in class discussion are good subjects for further investigation.

f. The executive trainer should within his geographical limits make it a routine procedure each day for one-half hour at least to circulate among the employees in a friendly, personal way to learn their names, talk about interesting matters, make and maintain contacts, and particularly to search for finds.

12. With all these records before him the executive trainer is prepared to begin the *sifting process*. From the employment files he secures personal history records and such others as are at hand. Then he proceeds to the *personal interview*, the crux of the process of selection. He must in this interview decide whether or not the person is not suitable for consideration, clearly suitable, or worthy of further investigation.

One obvious pitfall to be avoided by the executive trainer is the danger to a prospect of raising his expectations by an unusual interview with a major executive. But a resourceful executive trainer will use a number of devices. He will sometimes conduct the interview casually on the floor when he is mak-

ing his rounds. He may call the prospect to the office for some other obvious reason and naturally fall into conversation with him about things in general. He may have so many young people coming to see him that a call is not an unusual occurrence, or he may invite the employees to come to him about any of their problems.

In preparation for the interview, the executive trainer prepares a list of items. He will secure information on each item. He will realize, of course, that there are some data that cannot be secured in an interview. Specifically, he cannot tell how dependable, honest, persistent, or loyal the person being interviewed is. On the other hand, there are a number of items on which he can form opinions in the interview. These include such as the following: the appearance and manners of the prospect; his likeableness; his attitude toward the organization's kind of work; his outside interests and hobbies; his forcefulness; his mental brightness in conversation; together with any disagreeable mannerisms that may prove to be handicaps. Preferably, a form should be prepared upon which to record the impressions of the interview. Again, I am of the opinion that an informal wording of the interview findings is preferable to the scale form.

In conducting the interview there are five simple suggestions which help to make the interview productive. These may be hit off with five verbs: *relax*, *listen*, *question*, *decide*, and *quit*. A good executive trainer always tries to place the interviewee at his ease, as soon as he enters the office. Relaxation is essential to psychological probing. The executive will be offhand, free, and as humorous as he is able to be. Similarly, the executive must be a good listener if he wishes to learn as much as he can within a given time. Sometimes it is much more difficult to listen than to talk. The executive has his stipulated items in mind and will ask the questions necessary to cover those items, but he will do little talking except in the form of questions. He will do no more talking outside the asking of questions than is necessary to get the interviewee to open up. As the interview continues the executive makes up his mind about the items upon which he is seeking information and jots them down, at least mentally. When the interview is complete he has the ability to indicate tactfully that it is over.

The worst possible interview that can be held is one which breaks all these rules. In such an interview the executive is so tense, high strung, or busy that the interviewee is embarrassed. The executive does all the talking but asks very few questions. When the interview is over he is not able to sum it up in his own way, and after the interview is really over the conversation drags on until the interviewee feels that he cannot spend any more time on it.

13. If the executive trainers' decision is favorable after he has collected and weighed all the available data, the individual is entered upon a prospect list for training and for further study. The first hurdle has thus been jumped by the prospect, but before he is transferred from the prospect list to the available list it is obviously necessary that some time be spent in extended preparation and training during which he will need to be given comprehensive tests of a practical sort upon all those items which are necessary for executive success.

THE DEVELOPMENT OF EXECUTIVE TALENT

BY W. W. CHARTERS, *Director, Bureau of Educational Research, College of Education, Ohio State University*

Training Is a Major Function of Management. In the past, but decreasingly in the present, the position was taken that management was not concerned with training. The manager of a department, under those conditions, was selected because of his knowledge of technical processes and because of his ability in getting work done. The most highly praised executive was the one who used the method of assigning tasks to a subordinate and leaving him largely alone to work out his own salvation. This was done for the stated reason that such a process developed the initiative and self-reliance of the young man.

This method of assigning duties without guidance is slowly becoming obsolete. Its decrease in popularity is due largely to the fact that the mistakes which are made when no guidance is given have become so serious that they are reflected in the prices charged to the customer and in the profits accruing to the shareholders. No organization, except an extremely wealthy or an extremely selfish one which has no regard for the welfare of the consuming public, can afford to follow the policy of making assignments to young executives without direction. Keen competition, which demands the lowest possible costs of production, is dealing this method a death blow.

The policy of assigning duties without direction is wisely applied only when we deal with able executives. Clearly, every corporation ought to have within its organization a number of executives who are so expert that departments and projects can be assigned to them with the expectation that the work will be well done because these executives know more about handling the problems than do their superiors or the board of directors. But even boards of directors and major executives closely study results and evaluate the results of such men—for Homer may nod, and the superior executive may make mistakes. In fact, as business becomes more complicated the intelligent executive constantly seeks for advice in all directions.

The principle that training is a major function of management is growing in acceptance. The statement that training is the only function of management is too extreme, because obviously policies have to be set up and decisions have to be made before work can be delegated through training. Yet executives are realizing that they can delegate economically only as they train with thoroughness. As has just been said, the overhead cannot stand the expense of delegation without training. On the contrary, that executive who has a well-trained force secures the leisure and the absence of strain that enables him to attend to those major problems of policy, which constitute his most important function. A little time spent on training while assigning duties relieves the executive of the nagging worries that arise from uncompleted details. A good trainer works as efficiently as an automobile works when it is hitting on all six cylinders and running on the level.

Books and classroom instruction are useful in learning backgrounds in training, but techniques of management are learned best on the job. When

a trainer wishes his boys to get the principles of business he may send them to books; but when he wishes to teach them how to handle specific problems within the organization he puts them to work. It is obvious that the author of a book on management must deal with general principles because the appeal of his material is wide. Moreover, the author will want to deal with generalization because one of the functions of a book is to present principles and generalizations which can be applied intelligently to many different types of situations. The book which deals only with a detailed method of handling specific situations has its place as a manual, but its scope is confined to the organization whose details it describes.

The responsibility of teaching management techniques, therefore, belongs to the line executive. He, and he alone, is able to provide the information that is necessary for the polished art of management. If he fails to recognize this principle and to put it into performance the subordinate is left to his own devices. He must learn the techniques of management by the wasteful trial and error method, which is being abandoned by progressive managers.

This principle results, in its application, in a system of decentralized training. The office of every executive is a little schoolroom in which one or more students are being taught. Centralized training has been advocated by many as the superior method of training. The conviction is based on the fact that in centralized training you can secure people who know the techniques of training; but its weakness as a system lies in the regrettable fact that these people who know the techniques of training neither know the techniques of management nor have the authority which carries conviction. In choosing between line executives who are not conspicuous trainers and excellent teachers who do not know the techniques of management, the choice lies increasingly with the selection of the line executive.

In this case, when training is decentralized and put into the hands of managers who are not expert in training, the function of the training department is increased. One of the functions of the training department becomes that of helping the manager improve his techniques of training. The training department provides materials, suggests ideas, frequently gives instruction in training to managers, still more frequently watches them at work and trains them on the job, and checks up for the major executives on the efficiency of the training which the manager gives to his subordinates.

Types of Executive Development. The most common method of choosing executives to be trained is to watch young men on the job for which they are employed and select those who seem to possess the qualities which will be useful in management. The most common method of developing these men is to let them continue on the production job, give them at first a few managerial responsibilities and later, as time goes on, increasing responsibility as they prove their capacity to handle the new duties assigned to them. In this way, at a slower or more rapid rate, depending on the individual, he grows into a more and more important executive. Ordinarily this junior is expected to take the problems assigned to him and work them out to the best of his ability. Some executives give him a good deal of assistance; others give him less. The amount and kind of training are unplanned and dependent on the individual preferences and abilities of the manager. Such training is usually

unorganized and depends upon chance so far as the organization as a whole is concerned. In other words, some of the juniors receive broad training from the manager and some receive none.

To make this training more efficient by calling attention to what the manager may do with intention and through planning, in addition to what he already does by accident, is one of the major functions of this report. For we believe that this method of training while the junior is producing is extremely valuable and neither can be nor should be eliminated in many organizations. We are convinced the possibilities of training that can be given in this type of situation have not been fully realized by the average manager who is confronted with this responsibility.

A second method of development is used in a number of organizations that require a larger number of executives than can be secured by the production method of training, which has just been described. In some companies the raw material which comes in through the employment office is frequently of a quality so low that the number of prospects is too few to fill the executive vacancies that occur. It sometimes happens, for instance, that when lower positions require little more than an eighth grade training, it will take a long time and may be impossible for the beginners on production jobs to develop the background and skill necessary for filling executive positions.

In such cases many organizations have made a short cut of the process. They have either taken young men out of production or have brought in from the schools and colleges young men who seem to possess managerial qualities, and have placed them in groups called the "flying squadron," "floaters," "students," and so on. Such a procedure has to be handled with great care because of the danger of training thereby a group of executives who have only a superficial knowledge of the business. This is cared for by a long continued process of routing young men through the different departments in order to secure the necessary technical background; by giving instruction in classes in order that the prospects may secure the proper functional background; and by providing them with other methods for securing a good personnel background.

We may contrast the two types mentioned by saying that *in the first type production is major and training is minor; while in the second type training is major and production is minor in importance.* As to which of these types is the better no one can decide. The first type works better in some organizations while the second works better in others. As to which type is best for a specific company must be left to the judgment of the company in question. As a general rule, however, we may say that if the production type is used then training must be safeguarded. If the training type of development is used, production must be adequately cared for to the point where the junior will have a knowledge of production methods adequate for managerial judgments.

To one who has followed the discussion closely it becomes apparent that whichever method is used a knowledge of the techniques of training is essential. A manager who has charge of young men under him is benefited by all the suggestions about training that he can get and, obviously, the companies that take the junior off production must likewise be aware of and utilize the

best methods of training. Our problem is how to improve training whichever method is used.

Managerial Background. The discussion of this complicated question will be clarified if we distinguish between two elements in executive training, namely, the acquisition of background and the learning of the techniques of management. It is a matter of common knowledge that an executive with a broad background is, other things being equal, more effective than one who has a limited background. Indeed, the acquisition of background is the chief argument in favor of a college education as a preparation for business.

Managerial background may be of three types. There is, first, what we may call the *functional background*. By that term we mean a background which is made up of the underlying principles and functions of business, a knowledge of the products of the company, and the place of the organization in the world of business. An executive with this functional background knows also the function of each of the divisions within the organization and apprehends the processes of marketing, production, distribution, and organization as they apply to his establishment.

In addition to this functional background there is in many institutions a need for a *technical background*. By this we mean a familiarity with those processes which are carried on within the organization to produce whatever product it is the business of the company to manufacture. For instance, in the production of steel it is recognized by those who know that a young man, even though he has an engineering education, needs to know how the product is manufactured through all its steps and processes in order to become a wise executive. Consequently, we find in organizations that use highly specialized technical processes that the common procedure is to route the prospective executive through all important divisions at a leisurely pace, so that he may in truth, as well as in appearances, master the essentials of the technique and thereby acquire this necessary technical background. This applies with equal force to the juniors who have been picked out of some one branch of the organization as to those who are brought in from the outside to take special training.

In other organizations, however, it frequently happens that a detailed technical knowledge is not of as great importance as has been indicated. Then the period of routing is shortened. Although it is dangerous to make this routing too short, it is not always necessary to route the junior through all the departments of the organization. For instance, if the executive to be trained is a foreman, his knowledge of other departments may be gained through talks and lectures and study, and his routing may be confined entirely to those departments through which the flow of production progresses. He is benefited by being routed through the superintendent's office, through the supply department, through the records department, and through the department which receives his material when he is finished with it, for the purpose of understanding clearly what his immediate contacts are within the organization. Again, a junior in the financial department will be routed through the divisions within that department, but he probably does not need to get into personal contact with the sales department. On the other hand, the junior in the sales department may very well be routed through the production depart-

ment at a rate sufficiently rapid to enable him to see the relation of production processes to sales product. The principle to be followed is this: Once the amount of technical background needed by an executive has been determined, he should be given those contacts within the organization which are necessary for him to acquire the information and understanding that he needs.

The third element in executive background is not stressed so greatly by our correspondents, but we know from our contacts with business that it is considered to be of primary importance. This we may call the *personnel background*. By the term we mean a knowledge of people and an appreciation of their motives, their intentions, and their ambitions. This type of background cannot be completely learned from books, although up to a certain point books are extremely useful. Much of it is learned, if learned at all, in the rough and tumble contacts of juniors with people, and it increases with age if the individual is sensitive to the feelings and actions of other men. Some people naturally possess this ability or seem to acquire it with little effort; others are extremely slow in developing understanding. But in either case understanding can be deepened by training.

Techniques of Management. The polished executive must, in addition to background, possess skill in the techniques of management. The techniques may be studied from three angles. The junior may secure information about the techniques by finding out what the problems of management are and learning how they are solved. Such an individual would be called a well-informed person. If he is well-informed he is usually of the bright, scholarly type who gathers information because of intellectual curiosity and retains it because of a good memory. But information about techniques does not guarantee skill in management. A good manager must not only know good techniques, but he must be able to put them into effect. In other words, we may approach the techniques of management from the angle of action. A course of training is successful to the degree that the manager knows what is to be done and actually puts his assignments across, whether they are assignments which depend on himself alone or on his ability to get other people to perform assigned duties for him. To turn information into action it is necessary to give the junior responsibility, and the training involved is concerned with methods of putting things across.

It is important also to approach the techniques of management from the point of view of the qualities which a good manager must possess. Frequently when a junior's performance is not good it can be improved by the correction of a trait of personality. A junior may be a good manager except for the fact that he is not courteous; or he may be lacking in self-confidence; or again in personal appearance. He may be very intelligent, possess a wide range of information and, on the whole, be an able executive; yet he may lack one or two more or less important qualities. In such a case training may greatly improve the performance of a junior by working directly upon those qualities of management in which he is deficient. Parenthetically, it may be said that if the qualities in which he is deficient are extremely essential to successful management, the failure to possess them may eliminate him as a prospect for advancement. Just what qualities yield to development and what do not is not at present scientifically known. Consequently the lack of

qualities as a deterrent to promotion must necessarily be left to the judgment of those concerned with promotion and with further training.

Techniques of Training. To organize the many methods which are used in training executives I have put the material into graphic form in the accompanying chart entitled "The Techniques of Training."

In the chart it will be noted that we have along the left-hand side techniques entitled school, outside courses, company courses, and so forth. The six columns to the right are divided into two groups of three each, one entitled "background," the other "techniques of management." The three columns under background refer to functional background, technical background, and personnel background. The three columns under techniques of management mean information, action, and qualities. The checks mean that schooling, for instance, will provide functional, technical and personnel background, but will not provide the techniques of management. Reading farther down the left-hand column we note by the checks in the column that routing, when properly conducted, can give training in all phases of the project. We shall now proceed to a discussion of the techniques of training.

Preliminary Schooling. It is obvious that the school which the junior attends before he makes contacts with an organization may be of value in

developing background. If he has been a student in a college of commerce he secures a functional background through a study of the principles of production and distribution, and to a certain extent he may secure information which will develop a technical background. In colleges of engineering he develops a technical background and perhaps to a smaller extent a functional background. Increasingly in both types of school he acquires a personnel background, although only recently has much attention been put to problems of personnel in professional schools. In colleges of liberal arts a background is developed of a much more general sort than is the case with professional schools that prepare for business.

Chiefly because of this background value do we find companies favoring graduates of professional schools. It is realized, however, that because of two facts all positions do not need to be filled by college graduates. In the first place, some minor executive positions require little background for reasonable efficiency in carrying on the work; in the second place, there are many bright young men who in the absence of an opportunity to attend college have acquired the fundamental principles of their jobs within the business itself. Because of their superior intelligence, thoughtfulness and curiosity, they have been able to gain a knowledge of business and of life sufficient for practical purposes.

The Company Library. Whether the prospect has attended college or not many organizations maintain generous library facilities, sometimes to provide technical and functional information, frequently to furnish ideas about the principles of psychology which underly methods of handling men. Some of our correspondents presented us with lists of titles obviously selected with great care and with the purpose of providing both techniques and principles.

The important point about the library, they feel, is that it should be well chosen. In some cases carefully prepared courses of reading have been worked out with guides to indicate what to look for and with directions about how to study properly. In a large number of organizations trained librarians are in charge. In some of these organizations the librarians are extremely expert reference workers, who in addition to handing out books to applicants select books on topics and even gather original data from many sources. In view of the demonstrated usefulness of a library in an organization the problem of expanding the function of the library and securing the expert service of a librarian is one that deserves much more careful attention than it has had by many organizations up to the present time, and in this service the junior executive may share.

Where organizations do not maintain libraries of their own they occasionally have close relationships with the reference department of a public library. This unselfish institution is willing to go to great lengths in providing printed material which will be of value to an organization, and frequently arrangements can be made to have a private branch of the library installed in the company plant.

Outside Courses. Business background is provided in many cases by formal courses of instruction. Sometimes these courses are prepared and conducted by outside organizations such as the Y. M. C. A. night schools, correspondence

schools, and the like. In such cases it is a common practice for the company to pay tuition charges or half the tuition charges when the student has successfully completed a course. In a few cases it is felt by the management that the student should bear this expense himself on the ground that he is personally deriving the benefit. Such managers also believe this is one method of weeding out those who lack ambition by reason of the fact, that if a man does not care enough to take a course and pay for it himself he does not possess the amount of initiative necessary to be a good executive. It appears to us, however, that the better plan is the one by which the company refunds the tuition when the course has been successfully completed. One such company, during the year 1927, refunded over \$5,000 to its employees in payment for tuition in outside courses satisfactorily completed.

Company Courses. A large number of companies carry on courses for juniors within their own organizations. Sometimes these are given on employee time, more frequently on company time. The argument in favor of devoting company time to them is based on the recognition of the benefit the organization derives from having the junior take additional training.

The advantage of company in contrast to outside courses lies in the greater control which the company possesses over its own courses. Clearly, when a course is given on the outside it is ordinarily given as a background course, but it does not deal with the specific practice of the individual company in which the prospect is employed. A company course, on the other hand, can teach the principles and at the same time give specific applications of these principles to the everyday problems which the prospect meets. Company courses, therefore, seem to be preferred since they combine both background and techniques. They are, however, more costly, because the salaries of members of the educational department in preparing and giving the courses are usually greater than the total amount of tuition charges by outside courses. Nevertheless, the difference in cost is more than compensated for by the increase in the practical nature of the course for the employees of the organization. It may therefore be said that, on the whole, the officials in our corresponding companies are fully aware of the advantage to themselves and to their employees of creating educational opportunities such as these just described.

As is naturally to be expected the variety of courses is very great. One organization conducts a series of sixteen courses most of which are intended for executives. Other organizations have one basic course through which all juniors above a certain level are put. These courses meet once a week, once a fortnight, or more frequently. Under the best conditions, the students are given outside reading assignments, are subjected to written and oral quizzes, and are put through the same kind of intensive training as is given in professional schools.

We have in our possession outlines of these courses presented in great detail in mimeographed form and frequently in printed form, combined with information about who are eligible, what it is necessary to do in order to enter, and other like matters. Organizations demonstrate by their attention to the matter that they consider training to be one of the major functions of an organization.

It is quite natural that a good many organizations which route students through departments as part of the training program should use classroom courses as supplementary to that procedure. Consequently, we find many of our companies requiring their juniors in training to work in departments part of the day and attend systematic courses during the remainder or in the evenings. This combination is undoubtedly extremely valuable if and when the background work in the course is correlated with the practical work in the departments. A combination such as this is not difficult to provide if the executive trainer lays out the problems worked upon in the departments and the principles developed in the classes, so that they more or less approximately synchronize.

While we are on the subject of courses it is best to clear the discussion of two major problems relating to the training of men for executive positions.

Number of Men to Train. In setting up a program the executive trainer must determine the number of men to be trained each year. This becomes a crucial question because of the fact that when more people are trained than can be quickly used, the morale of those who have received the training is lowered. Wise administrative officers, therefore, recognize that unless there is wide expansion of the business there is need for only a comparatively small number of people in training. Whether the number is large or small, the trend of executive replacement in the organization must be studied so that just enough people are trained to care for the vacancies.

When, however, more people are trained than are needed the problem is handled in two ways. In some cases the men are placed on special assignments, attached to the research department or even, in some organizations, told that they are free to accept positions elsewhere. The more satisfactory method, however, is for management to make no promises. In such a case it says, in effect, to bright young men, "Here is an opportunity for improvement which you will be glad to accept without any promises or hope on our part that we can promote you. It may be years before an opening occurs. You will have to prove yourself; but in the meantime you will be better prepared for business in this company or elsewhere." By judicious care the hopes of young men who take special training need not be unduly aroused.

Cost of Training. The cost of training executives is of interest, yet we secured very little information on the question. Where the prospect is developed by the production method the training he picks up for himself costs the company nothing. Where he is taken off a production job the cost of training is as much, or nearly as much, as the prospect would be likely to earn on a production job of a minor sort. The method of determining the cost is to multiply the salary per month by the number of months in training and add such overhead as is necessary to carry out the program. Some of our companies estimate the cost at from \$1,000 to \$2,000 for a six-months' course. Another spends \$1,000 for a four-months' course. In this case the company operates a formal training school with a full-time instructor, and in addition makes individual allowances to men who might be separated from their homes while in training.

Several observers, however, make an important point. To offset the cost of training, the prospect produces certain intangible yet important results.

When he is keen and alert he is frequently, if not usually, the source of many good suggestions, the financial value of which is not easily estimated but the general results of which are, nevertheless, perfectly evident to the management. The general impression of our group is that the cost is not great in proportion to the returns received from the training.

This is particularly true when we consider that on the whole the percentage of men who remain with their organizations is unexpectedly large. Roughly speaking, about 71 per cent of the men trained for executive positions remain with their companies for a period of three years or more after training, and there are few losses during the training period. In two companies, however, it is noted that more than one-half of the men do not remain long enough to become of any real value. Yet this proportion is exceptional and is due to the fact that in both cases the training received fits the men for more attractive lines of work.

Lectures. We can now continue the discussion of the methods by which men are trained. In most companies, whether systematic courses are given or not, lectures are provided from a variety of sources. Speakers, with or without national reputations, but with some expert knowledge are brought in from the outside. Heads of departments, chief executives, and experts within the departments are likewise drafted and used. Frequently these lectures are run in a series at the rate of one every two weeks or one a month. Sometimes they center around one topic; sometimes they are selected to cover a wide range of topics.

It is apparent, of course, that results accruing from isolated lectures cannot be compared with those in which the lectures are organized into compact courses. The reason for this is that when a man takes a course he expects to work, but when he attends a lecture he expects to do little more than listen. Consequently most of what the lecturer says evaporates. But in a course the lecture is supplemented by the required readings of the notes taken on the lecture and by discussions, or even by quizzing on what has been heard and read. The student, therefore, is compelled to work and when he works, learning conditions which prevail in professional schools are more nearly approximated, with the result that the training secured by the student is thereby tripled or quadrupled. In this, as in all learning, one learns only as he puts thought and effort into study and the isolated lecture fails because it does not demand effort.

In one company the organized lecture course has been developed with a high degree of efficiency. Over 200 executives and prospects are enrolled in the course which is two years in length and consists of approximately fifty topics. These are given to the men on company time. One lecture is given to the whole group on one day of a week. The subject matter of the lecture is prepared with very great care, mimeographed, and handed out to the members at the end of the lecture. During the following week the group is divided into about ten smaller groups, each containing twenty-five members. These, during the interval, have read and digested the lecture and at the second meeting they discuss the material that is contained in it. In this way each of the fifty topics is covered in two years. This particular course deals with all phases of the business and is essentially a background course

designed to make the executive in one department acquainted with the major duties and problems of the other departments and of the institution as a whole.

Junior Organizations. A number of our correspondents speak with great enthusiasm of the value of organizations of juniors. One company has recently divided its junior executives into teams of two or three under a senior executive. Meetings are held on one night every two weeks, when these teams present their solutions of problems which have been given them in advance. These problems are real and are designed to give the men information about departments other than their own. Frequently the teams meet before the regular meeting night and discuss and consider fully the answers to the problems. They are privileged, as individuals and as teams, to ask questions of the executive in charge of the work to which the problem pertains, but must not ask him for a solution. Then, on the meeting night, two members from each team present a solution. All the executives vote on which has presented the best solution. This, I think, is a very clever and interesting device.

Other types of program are followed by these organizations. Sometimes the boys explain to the others the operations of their own departments and the difficulties they encounter in their work. This naturally leads to a free rough and tumble adolescent discussion of the problems of the organization. While few new solutions and fundamental facts may be discovered by the boys, they begin to sense the problems of management and get that breadth which comes from a knowledge of the problems of departments other than their own.

The leadership of the group sometimes rests with the training department, yet on the whole it is found to be more satisfactory to have an outstanding line executive interested in juniors become the active manager, while the training department takes charge of the details and sees that he carries on his work effectively.

Executive Conference. Another form of instruction that is extremely valuable for juniors is attendance at executive conferences. It is a growing practice to allow young executives to meet with the older executives when the problems of management are being discussed. In all companies, of course, executives get together from time to time for conferences upon important problems connected with management. In some cases it is the practice to require, and in other cases to invite, the assistants or selected assistants in the departments to attend these conferences with their chiefs. By such a procedure the young men see the problems from the executive point of view, and therefore take a more intelligent view of their own problems.

In addition to executive conferences training conferences are frequently held by major executives who feel the need of talking over the problems of handling people with their foremen. They give them instruction in methods or draft the training department to lead the discussion. To these conferences the juniors are frequently invited. In still other cases a limited number of juniors are sent to association meetings at company expense as a reward for bits of work well done. Such a procedure is, of course, limited by cost, but within those bounds the value to the junior in broadening his horizon and giving him enthusiasm for his job is clearly recognized.

Conversations with Managers. One of the most fruitful methods of training juniors is through conversations in which the manager informally talks over with the prospect the problems immediately confronting him. It must be realized, of course, that the executive is a busy man and often has no time for conversation that does not deal directly with the duty at hand. But it is very important for executives to take time to relax and chat with juniors about policies, methods, and reasons for decisions that have just been made. Juniors on their part frequently feel that their greatest stimulation has come from these short and informal periods, when the chief takes a few minutes off to talk over the considerations that have influenced him.

This ability to talk about problems to younger men instead of telling them what to do is a rare gift which not all executives develop naturally. It is very much easier and less time consuming for the executive to tell his subordinates what to do, or to turn tasks over to them with the bald command to take charge of them. From one point of view more time is consumed, and time which often appears to the busy executive to be very valuable, in talking about problems and methods of solution and major policies. Yet, in the long run, time is gained when such talks are properly conducted, because the aid given by the subordinate becomes much more intelligent. He is, on the one hand, better able to think problems through for himself and, on the other hand, he sees the reason for what is done, whether the reason be good or poor. He is, in short, by this means taught to think under guidance and thereby avoids some mistakes. He, also, learns some new methods of doing things which he might never acquire by himself through his own gropings.

Absorbing Ideas. One of the main problems of the junior in training is to become aware of the problems of management. Many people look at things with their eyes yet do not see them with their minds. There are subordinates in front of whom from day to day problems pass of which they are not at all conscious. The good junior, therefore, is an alert young man who watches what is going on, listens in on conversations, and through his mental curiosity finds out what is being talked about and what the topics of conversation mean.

Someone has said that the chief reason why an expert workman may fail to become a good executive is that he is unable to see the operations of his department from the point of view of management. This I believe to be true. If it is, then one of the important problems in the training of juniors is to get them to see, to realize, to feel, and even to list the problems which come through the office of the chief who is coaching them.

A number of interesting devices are used to help the junior absorb the managerial problems of a department. One organization uses the very fine device of requiring the junior to read the correspondence files so that from the perusal of their contents he can make a list of the questions that come to the manager for disposal. A rather complete file for a year in a company where matters are disposed of largely by correspondence provides a very fruitful source for locating problems. Other companies, that do not have their files so compact or have not thought of using them, frequently assign to the junior the reading of the incoming mail for the same purpose and, later, the reading of the material in the filing basket to see what disposal has been made of the problems.

To catch those problems which are settled orally it is recommended that during the period of training the junior have the opportunity to sit beside the manager's desk and listen to the interviews that take place, and make notes of the problems which arise. This procedure can easily be handled so as to avoid embarrassment. If a caller has a private matter to take up with the manager it is a very simple matter for the manager to sense this and give the junior some commission which will take him out of the office. The situation is not very serious because nine-tenths of the problems which come before the manager under whom the junior is working are impersonal and public within the organization.

As a result of this absorption of problems and managerial atmosphere the junior is prepared at any stated time to make a classified list of problems of the office, and he will undoubtedly have a good deal of information about how the manager disposes of them.

Routing. In many organizations training is given by routing prospects through those departments which are related to the one in which he will work. In some cases he is routed through all the major departments; in others through allied departments. A decision as to the number to which he should be assigned is dependent wisely upon the number with which he needs to become acquainted in order to fulfill the duties to which he may later be promoted. A junior whose ability will probably not lead him beyond a minor executive position will obviously not need to receive a training as broad as that of one who seems to possess superior executive ability. Moreover, a very large organization, with parts sharply differentiated in function, may not demand for any of its executives below the major level a broad knowledge of all departments.

A Definite Schedule. In routing juniors through departments the first essential is to provide a definite training time schedule. This will be a general training schedule when it is the practice of the company to route a relatively large number of young men through the organization year by year. It may be an individual schedule when the routing is less frequent, or when the prospect is being prepared for a special type of position. In either case the schedule must be clearly and definitely worked out.

Junior Specifications. In diagnosing a routing program which fails to train the prospect, the first thing to investigate is the specifications. I know from reading the reports of our correspondents that many companies do nothing more than turn the junior over to a department to work in it for a specified length of time, and leave entirely to the manager the assignment of duties. Naturally one can forecast what will happen when this extra load is put upon the shoulders of many busy executives. The prospect will have to pick up for himself what he learns.

Companies that give more attention to training, however, send the junior into a department with exact specifications of what he is to do. Sometimes he is given a list of dozens of questions for which he is to secure the answers while he is in the department. We believe that the more detailed and numerous the questions, the more the learner will get out of his experience. We have in our correspondence samples of printed forms prepared by the training department to be used for this purpose. and as much care is taken in pro-

viding specifications for the junior on these forms as is taken in preparing blueprints for the production department; for the organizations that follow this practice realize that the training of their future managers is of more importance than is the manufacturing of products.

These specifications sometimes show the total number of days the junior will be in training; the list of jobs to be covered in each department, the time to be spent on each job, a list of important points to be noted in the department and on the job, and points to be looked for and considered when making a job analysis.

Experience in a department with such detailed and careful specifications at hand is so much better than the mere assigning of a man to a department that no comparison can be made between them. Assignment without specifications is futile and foolish.

Manager's Specifications. It is perhaps not necessary to say that the manager to whom the junior is assigned should be provided with a copy of the specifications given to the junior so that he may intelligently assist the junior to do what is expected of him. It is, however, necessary to add that the manager should be given such other specifications and information as will help him better to assist the apprentice. The methods of coaching the junior are ordinarily a matter of general conference and follow-up by the executive trainer. When the manager has learned how to cooperate in the case of one junior his methods will not materially change with others when they are assigned to him at a later date. Some executive trainers hold conferences with the manager on the subject of helping the "floater," sizing him up, reporting on his work, his strength, and his weaknesses.

Production Standards. There are differences in practice with regard to the standards set for the productive work of a member of the flying squadron when he is in the department. Some of our correspondents state emphatically that when he is placed on a job in a department he is subjected to the same standards as the regular employees in the department, and he stays with the job until he has reached that standard. They repeatedly state that no distinction is made between the standards set for a visitor and those by which permanent employees are measured.

On the contrary, other companies send the man into a department with the major purpose in mind of giving him acquaintance with the job rather than skill in performance. They feel he has gained all that is necessary when he has done the job a few times so that he gets the feel of it. Which of these two requirements is superior I have no way of determining. I can see that in some companies, particularly in highly technical production plants, thoroughgoing skill on operations is essential. I can see, on the other hand, that such a requirement might lead to a great deal of waste, when the requiring of the last 10 per cent of skill, which takes so long to get, may be of no particular value to the junior when he handles managerial problems affecting these departments.

Managerial Problems. At this point in routing, it is important to revert to our discussion of managerial problems under the topic entitled "absorption." The prospect may be assigned to a department for as long a period as six-months or a year without gaining anything except a technical skill and

later a technical background. His training may be of little value in preparing him for managerial duties, and the cause lies in the failure of management to introduce him to managerial problems.

If, therefore, the prospect is to receive any value from his contacts with the department he must at some time or other be brought into contact with the managerial problems of the department, which should be included in his specifications when he enters. He should be expected to secure information about the problems which confront the management and similarly the manager should be instructed in his specifications to make it possible for him to secure this information. Methods of bringing this about have, in part, been described, and will be reverted to in succeeding topics.

Manager's Reports. While the prospect is in a department it is expected that the manager make reports upon the work he has been doing. This report may include such topics as a production record, his ability to get along with other men in the department, and a rating of his personality. Mention should be made in such reports of his points of strength and weakness. These reports are made periodically, sometimes once a month, sometimes at the end of the assignment period. Frequent reports are preferable.

It is pointed out by our correspondents that these reports serve a double purpose. On the one hand, they give the executive trainer and other executives a knowledge of the efficiency of the prospect and, on the other hand, they compel the manager to size up the prospect from time to time. Printed forms are provided for this, sometimes in the form of rating scales supplemented or not by a report of the essay type to which attention was called in the preceding paper on the Discovery of Executive Talent.

These reports are sent up through the executive trainer to the major executives and sometimes are made the subject of conferences. The purpose of this procedure is to keep management constantly informed about the prospects in training who from time to time are considered in filling vacancies.

Two companies mention the plan of having the junior rate himself. They ask him to report on what he has been doing, how well he has been coming along, the difficulties he has met, and what he can do to improve himself.

They also require from the junior an extended report upon the specifications he took with him into the department. When he has been asked to secure the answers to questions, the answers are sometimes required in written form chiefly as a means of getting a clear idea of his ability. Sometimes it is found that the suggestions which these people make are of direct use in modifying the methods of the department and as such are of value to the business.

Assigning a Wide Range of Duties. We shall now turn to a more intensive analysis of the coaching duties of the manager. We do this for reasons stated above. Courses and classroom instruction will not produce a manager; he must have a knowledge of the techniques of handling specific managerial problems. Learning to perform production tasks will not guarantee that the individual has knowledge or skill in handling managerial questions. The training department can at best provide directly only background information. The boy, if left to himself, will make too many mistakes. Therefore, personal contact with the manager is the heart of the training program.

A manager, in training his assistant or any other junior assigned to him, will first of all make a job analysis of his duties for the sole purpose of seeing that while the subordinate is under him he gets contact with a complete range of managerial duties. . The value of making his formal list lies chiefly in two facts. First, the manager may not think about assigning the young man to some of his duties and, secondly, if he has a list before him as a check he is not so likely to give the junior the most pressing problems and forget to give him experience with other problems which perhaps the manager himself prefers to handle.

The manager will assign problems and duties to the junior. Sometimes these are duties of execution which he will perform as an assistant and see that they are carried out. In so doing, he is given that kind of responsibility which carries information over into action. These duties will grow in variety as the capacities and the ability of the junior to handle them is demonstrated. In addition the manager frequently assigns special problems for investigation. In every well-run department the manager has investigations which he would like to carry out if he had the time, and such projects are exactly the type of thing that helps the junior gain insight into the business.

The junior, in making these investigations, is expected to stay with them for a length of time sufficient to enable him to know the situation so thoroughly that he can present recommendations or suggestions to the management about what should be done. In fact, this ability to dissect what he sees, to get at the heart of a problem and to present it in a clear form, is one of the most important results to be achieved from these learning exercises. It is a matter of common experience that many people who know a great mass of details are not capable of seeing the central ideas running through them. And the man who is not able to analyze with some skill is lacking in one important executive quality.

As a supplement to this type of exercise the junior will be expected to present formal recommendations and reports to the management in order to give him practice in getting things across. Many superior analysts, thoughtful men, can work out a good solution to a knotty problem but are quite incapable of selling it to the management. They may be diffident; they may stand in awe of management; or they may be quite ineffective talkers. A trainer will, therefore, do all that he can to help the junior make a good case for himself when he has definitely made up his mind as to what should be done.

Correcting and Disciplining. The foregoing description of methods would not be complete without conspicuous mention of the responsibility of the manager to praise, criticize, and discipline. Only occasionally do we find men who do not need some discipline. If they are conscientious they need always to be praised because they are filling new positions and are not sure how successful they are in what they consider to be very important undertakings. But praise alone is not sufficient. They need constructive, intelligent, thorough-going criticism of their methods through conferences and interviews, through suggestions and advice. The background of such contacts should be free but vigorous, and the standards of judgment should be high. Since drastic criticism is necessary for artistic success in management praise should be given generously, whenever possible, as a counterbalance.

Giving Responsibility. If we examine the chart presented and recall the fact that the column that refers to action is the one that stands for information changed into performance, we will see the importance of placing responsibility upon the shoulders of the junior. This responsibility may be either personal or social. In giving personal responsibility the prospect carries through assignments which depend only upon his own efforts. Yet much more important are those assignments in which he has to handle people. These should be such as to require him to direct others, to carry on conferences with them, to train them, stimulate them, necessary to discipline them. And the junior should have his responsibilities increased as rapidly as he shows the ability to take on new and different ones. It should be pointed out again that giving responsibility by merely assigning the task to be done and holding the prospect responsible for the results is a much more wasteful procedure than to assign and train and hold responsible.

As responsibilities increase some use has been made in one or more companies of what is called the "put up" method. By this is described a policy of management to demand that the subordinate executive put up to his chief only those problems with which he has difficulty. This device increases the confidence and discrimination of the junior by getting him to distinguish clearly between those things which he has been taught to do and should do without help and those problems which are new and on which he ought to ask for guidance.

Trait Development. Our correspondents feel that the manager must pay close and serious attention to the development of managerial qualities. It frequently happens that the young man inducted into a position of responsibility lacks in one or more of the four traits which are fundamental to management. He may at first lack dependability and fail to carry through with completeness and efficiency the tasks assigned to him. He may likewise lack in vigor, sometimes because of lack of self-confidence and at other times because he does not naturally possess the quality to a high degree. Indeed, there is some question as to whether or not an individual who does not possess personal, physical, or mental vigor to a high degree should be trained to a major managerial position. On this I have no opinion. I have seen a number of very successful executives who were not of the driving kind and who from outer appearances were lacking in a conspicuous amount of personal vitality. But what they lacked in vigor they seemed to make up in wisdom and shrewdness. The junior may also be lacking in that resourcefulness which enables him to think out new solutions for problems, and particularly he may lack that trait of personal leadership which enables him to lead his subordinates contentedly to the completion of all necessary duties. All these traits and others are carefully watched by the manager who wishes to make the most of the material entrusted to him.

Training Programs in Use. I am impressed by the one-half dozen or more carefully thought out training programs for executive talent which were submitted in our correspondence. I am impressed with these because they are good and particularly because they are samples of what should be done by every organization interested in the training of junior executives. Training suffers seriously in many organizations which I know from a lack of definite-

ness and permanence. It is seldom possible to go to a training department and find in one place in permanent form all the training materials that have been used. They are usually found scattered here and there, in one place or another, and in some organizations it is not possible to find important material anywhere on the premises. As a result of this, there is no continuity in the program; when changes occur in the staff, material has frequently to be prepared a second time. To obviate this, I am convinced that care must be taken to preserve permanent records of all materials in bound form and in an appropriate place. The same care should be taken of training materials that is now taken of the records of materials in the comptroller's office.

Frequently in training departments we find that scattered effort is the rule. Nothing is nailed down, effort is wasted, time is lost. It is, therefore, encouraging to see in a number of substantial organizations that these defects are being corrected, that definite programs are worked out with very great care and in adequate detail, and that materials are preserved in permanent form. The lack of system to which I have referred is incidental to a young movement. In time, as the procedures become crystallized, the hazy and temporary nature of the work will disappear. But if attention is paid to permanency the progress will be much more rapid.

The Manager as a Trainer. A discussion of the training of executives would not be complete without a consideration of the willingness of the manager to train those who are under him. In some organizations the managers fail to take training seriously for two reasons. They may feel that they do not know enough, or they may be unwilling to train for fear they train themselves out of a job. It is natural for an executive in a certain type of organization to hesitate to begin such projects, because he knows that if he trains an assistant well he may himself be decapitated at some inopportune time. This, however, has not been reported as a common attitude by our companies. Rather they feel that when a manager does not train it is due either to a misunderstanding of his function as a trainer or to a lack of skill.

To provide incentive several methods are reported. First among these is continued emphasis on the policy that training is a function of management. The general manager may continually put before the executive the necessity of having capable assistants. In some companies the manager is held responsible for a deficiency of well qualified assistants in his department. In many cases managerial executives let department heads know that their standing is improved in direct ratio to the improvement they achieve in this respect in their departments. In some organizations the training of executives has become so popular a policy as to be a matter of prestige when a department has a number of bright and well-trained juniors working in it.

The idea of training as a function of management is given publicity in other ways. One of these is the periodical conference held on juniors. In the ordinary routine of business managerial executives constantly talk over with the heads of the departments the qualifications of the young men under them. Major committees hold frequent or irregular conferences on juniors. In some cases at weekly conferences an effort is made to classify the bright young men of the company on a comparative basis.

We find, however, that the consideration most frequently stressed is the policy that promotion comes only when an understudy is ready to step into the position made vacant. The department heads know that if they are to be promoted they must be prepared to fill the gap they leave. This, of course, is not a rigid rule in all companies, but it is understood that advancement is easier when a competent assistant is ready to fill the duties of the person promoted.

A number of organizations attack the problem of stimulation directly by providing training courses for executives. Sometimes also outside courses are put on; at other times, the educational department holds conferences on training. In this way, many people who ordinarily would not be influenced by other incentives are slowly educated to see the value of training their men.

Controls. No program of training is complete without check-up and evaluation. It is necessary to see whether the manager is performing his duties thoroughly as well as to see whether or not the junior is developing executive ability. In general, the business of checking up and looking after young executives is delegated to one executive trainer. He is usually a member of the training department but may be, and sometimes is, a principal, a manager, or a member of the employment department. In some cases the direction of the program is given to a committee on special courses.

The most frequently used method of discovering how well juniors are progressing is by direct personal contact. In some cases the contact is as frequent as two or three times a week. And in any case it is, or should be, often enough for the executive trainer to know personally how well the individual is developing. These personal contacts are frequently supplemented by oral reports from the manager made to those people in the organization who are interested in the problem. In addition periodical written reports are received from the management. Occasionally, as has been said above, they are made in the form of rating scales. When juniors are pursuing company courses or outside courses progress reports made by their instructors are relied upon for information concerning attendance, punctuality, grades, personality, strength and weaknesses. In these formal courses the junior is submitted to oral and written quizzes. In some cases the general manager may have time to quiz them but, whether he or someone else performs the function, the student is sized up as he goes through the forms of learning to see that he has mastered his work in an intelligent way.

In a large organization it is a matter of necessity, and in a small organization a matter of wisdom, to maintain in one file all the records, reports, and communications about the juniors who are in training, so that at the appropriate time when replacements are to be made full information on all possible candidates may be easily at hand and quickly reviewed.

The reader who has had the interest in the problem to follow through this detailed presentation of principles and methods will realize the truth of what was said at the outset. We have presented more methods than can be found in any one organization, and this composite story of the good methods that can be applied will be of use not so much in its entirety in any one organization, as in its details for those companies that are interested in the problem and find suggestions which they believe will work successfully under

their particular conditions. The one characteristic that distinguishes efficient training of junior executives is the personal, man to man contact and the intelligent interest of the individual executive in the training of the subordinates who are immediately under him. Nothing can take the place of this.

INCENTIVES FOR EXECUTIVES

By HENRY S. DENNISON, *President, Dennison Manufacturing Co.*

Incentives for executives are much more widely used than is commonly known because the large majority of such schemes are not published—some of them being absolutely secret. Two or three investigations that I have known, not directly into the subject but into companion subjects, have disclosed that certainly more than two-thirds of the progressive concerns have some system of incentive for executives. We are equally safe in assuming that the day for description of one plan or another is at least well advanced. We have had a number of detailed descriptions; and they are increasingly available.

What is needed is a rather critical analysis of the real strength of incentives of various types. Let us take the separate features, as nearly as possible, of typical plans and try to make a preliminary analysis as to what each of these separate features might be expected to accomplish alone. The whole subject is, of course, in an experimental stage. There have not been in effect anywhere systems of executive incentives long enough to give us definite evidence as to their precise effects. Most of the schemes now in existence—a huge majority, I suspect—began after 1921. We can be excused from insisting upon final evidence anywhere in the subject, yet cannot be excused from attempting a preliminary analysis of what might properly be expected from the various elements of an incentive scheme.

Our company began in 1911 with the conviction that in the whole subject of profit-sharing it was the executives who had been overlooked. We thought of profit-sharing in those first days of this century as something that would be nice to do for poor and underpaid manual workers, and most of the profit-sharing ideals of that time built themselves around that consideration. Meanwhile, we were very seriously overlooking what the Englishman calls the "overlooker"—the supervisory executive group whose interest was extremely important for the concern. In our own concern we can at least be supposed to have expressed our cordial approval of the idea as a whole; and in breaking it up into parts and attempting to examine those parts critically we cannot be supposed to be "agin" it in any sense.

In order to make some sort of rough approximation of an analysis, I have divided incentive schemes into pairs of groups along eight different lines of cleavage and thus have obtained rather narrow areas, each one of which can be looked at separately. To phrase it differently, I have attempted to discover the elements of which the complex molecule we call an incentive plan is composed, in order to guess at the characteristic influences which might fairly be attributed to each of the elements.

There are incentive schemes which are built to apportion the incentive directly in accordance with the individual performance as contrasted with incentive schemes which apportion the incentive in accordance with a group performance; that is, incentive schemes dependent upon individual performance as against those primarily dependent upon the performance of a group, large or small.

There are cash incentives as contrasted with incentives in stock, and by stock I shall mean non-convertible stock of the company itself, assuming another kind of stock is simply cash one step removed.

There are incentives which are additional to a standard salary; a salary that compares with the market, as against incentives which replace a considerable proportion of salary.

There are incentives which are relatively uniform in amount—steady incentives, as against incentives which fluctuate rather widely.

There are incentives which are based upon a systematic scheme, a written down plan of things, stated in advance . . . each man shall get such and such a portion of something or other, as against the schemes which are arbitrary.

There are schemes which are public—that is, at least among the group involved, the basis of which is known in advance, as against schemes which are secret.

There are incentives which come to large amounts as against incentives of relatively very small amounts.

Finally, there are financial incentives as against non-financial incentives.

These artificial separations of incentive schemes are not mutually exclusive. Any scheme must consist of a great many of these elements; usually it is quite a complex molecule. Nor is any one of the divisions made, cash as against stock, etc., mutually exclusive in itself, since many incentive schemes have both cash and stock in proportion. But in order to see more clearly than we ourselves have yet been able to see into the true nature of the incentive plans which are being instituted now in really great variety, I am making this artificial division and focusing attention for the moment upon the mere "cashiness" of an incentive scheme and what it could be expected to do because of its cash, as against the stock or, shall I say, "stockiness" of a scheme, or what it might be expected to do simply because it is in stock. And so through all the other categories which I shall use.

Individual vs. Group Incentives. Let us consider first, individual incentives as against group incentives or, as stated before, an incentive based upon the recipient's specific and individual contribution as compared with an incentive in which he is simply one of a group, where the amount is dependent chiefly upon the work of the group as a whole, whether he scamps his job or does double or treble the usual job we can expect. Let us focus for a moment upon the bonus dependent upon the individual's work. Obviously we can expect such an incentive to be a strong spur to action. Not so obviously, however, it allows the recipient to set his own limits to action. We have grown righteously indignant for many years over the limitation of output under piece rates. If we are paying piece rates, we at least lay ourselves liable to a limitation which the man might want to set on himself. We don't get quite so indignant over the limitation which salesmen frequently set for

themselves when paid on commission. Yet it is common practice for the commission salesman to figure he has done enough for a day and quit if it has gone pretty well. As a matter of fact, they do say the movie business would suffer seriously in afternoon attendance if all salesmen worked all day. There is inherent in the idea "We pay you for all you do in accordance with what you do" a proper counterassumption: "If I want to quit, whose business is it?" "If I want to work harder, I can"; "If I want to work easier and take less, that's my business!"

The individual incentive, we must recognize, induces cooperation with other members of the group only to the extent that the individual supposes cooperation will serve his own ends. There is no incentive toward cooperation to a degree beyond that which the man thinks would help himself.

Individual incentive allows any degree of internal competition, yet has no influence against what might be a destructive competition. If an individual gets on better and makes a better showing by setting another chap back a bit, that is in the game too—or at least it is in the nature of the incentive that he shall as readily do that as advance his own case in any other way. We cannot look under individual incentives for the development of any wide spirit of cooperation. It is definitely an instrument for developing an attitude of each for himself.

My critical attitude in analyzing this subject attempts, at any rate, to be the scientific critical attitude. There are cases in organizations where just that development of a personal attitude of each man for himself may be the best sort of thing. There are places in our organization where the development of that attitude of each man for himself does us at least less harm, an almost inconsiderable harm. There are not many such places in our particular organization, but there are some. In apparently criticizing this or that element in incentives it does not mean, therefore, that they have no place—they may have a very proper place.

On the other hand, a group incentive based upon the performance of a group of people rather than one alone, obviously offers a weaker spur to action. It is perfectly possible for a man to scamp his job entirely. There may be another reason against scamping—the eye of the boss, salary, or something of that kind, but now I am speaking of what the incentive itself is to accomplish—nothing more. Obviously he can scamp his job 100 per cent and ride on with the group and get his share at the end of the year just the same. Group incentive, however, induces a wider cooperation than the individual incentive; and where cooperation is of major importance the group incentive must be considered. It can have a specific and active effect year after year towards knitting a group into a true organization. It helps build that organic unity which must exist if we are to call any group of people truly an organization.

A group incentive has a spur to action frequently overlooked, yet rather important, very much so in some special cases of group incentive. There is a type of supervision involved in group incentive that is quite valuable in certain cases—the supervision of the other members of the group. It is true in our own case, very greatly, that such supervision is not a critically negative supervision—rather it is constructive and affirmative. Our plan, I am

sure, has a greater effect upon our principal executives more by virtue of the possible criticism of their fellow executives, than by virtue of the cash in hand obtained at the end of any given period. That is partly because ours is not cash in hand, for the most part, but is stock in hand.

There is really a very powerful incentive to individual performance of one's own job lying in the opinion of the group one is working with, when that group wins or loses, shares in the profits that a group incentive scheme gives. In small teams of five or three workers in the factory, where the team is close together and can see what each member is doing, it has been repeatedly found that the new type of incentive to action is the criticism of the other members of the team for anyone who lies down on his or her job. Group incentive creates that rather new spur to action, one which under certain circumstances would be of the greatest value.

And that new incentive working in all grades, under favorable circumstances is the most powerful single influence upon our principal executives, due to our partnership plan. It is also a very powerful incentive in several of our group piece rates, or group task and bonus rates that we have throughout the factory.

Cash Incentives vs. Non-convertible Stock. Cash incentives, of course, have a strong spur varying in strength with the nearness in time or the remoteness of the day of distribution. It is at its strongest around the time of the distribution, and is weaker both before and after. It strengthens along towards Christmas time—the way a Christmas tree and Santa Claus work on the small boy—and survives for a longer or shorter spell, according to the man. Consequently cash incentives are frequently distributed at short intervals over the whole year. Where the cash incentive is given to the manual worker, who can be supposed to have a rather shorter range of imagination than others, it is often given once in two weeks in a separate envelope, or once a month. I should not be much afraid to maintain that putting a cash incentive in an envelope once a year for the manual worker is virtually without effect for ten months. Probably it is more without effect than we realize in the so-called higher grade worker, or the executive. In any case, it varies in strength, coming to a peak at the time of distribution.

Cash incentive, we must not forget, always involves a concentration of interest on the spending of said cash. That concentration works in all sorts of ways. It is popularly said (and our own employees very definitely said it in working out a plan for themselves) that the knowledge of a probable cash incentive coming quite universally induces spending among manual workers before they get it. So by their characterization, an annual cash incentive to the manual worker meant something he got that only partly paid the bills he had already incurred because of it. It was always spent beforehand, and usually overspent.

Let's look at the other extreme of that picture. I know of a case where a distribution to executives was so heavy in extraordinarily good times that it is actually true that several of the very important executives could not be found at their places of business for months afterwards—because they were playing the ticker and could make more money in playing with this large investment than sticking close to business. In other words, we must realize

when we talk of cash incentive that it is the total reaction we have to think about. It is not just the spur to do the job well that is all—it is much more complex than that. There are these other influences which will decidedly bear examination. We have to consider the intense influence of a cash incentive, the effects of disappointments, and the distractions I have already mentioned.

In the stock incentive (and there again I limit that to a not easily salable or actually transferable stock in the company the man is working for) we have, of course, a much weaker spur than the cash, so weak that in the early years—for at least two or three—we need expect no visible results to exist, perhaps none at all. To receive some non-convertible stock at the end of the year is obviously not an intense spur to hop around and do a great deal better job. To the man with imagination enough to see that it is actually good and amounts to so much in cash, it has some additional advantages; but to the average run of man it cannot be looked to as an active spur in many years. It has, however, this advantage—it has an accumulating effect which is a steady one.

If the incentive plan gives stock each year one can at least be sure of one thing—the man has the last year's incentive still on hand. Being non-salable, he cannot get rid of it, and this year's incentive adds to it. One has (and this, of course, is again in accordance with our own experience) an incentive which practically begins at zero, starts very slowly, but always grows in the depth and strength of its power.

The cash incentive requires repeated doses. A single dose of last year is done for when it gives out. If one has no more next year the effect is gone. The stock incentive has a persistent effect. It arouses the complex of motives which are very powerful—what we call the sense of proprietorship or ownership—something fairly deep in human nature. Having stock in the company, being a proprietor—even to a small extent—has a distinct and decided effect upon people by its own virtue.

There are not two kinds of incentives, one wholly cash and one wholly stock. As a matter of fact, most stock incentives depend at least upon the cash dividend to give cogency and value to the stock itself.

The Bonus. In an incentive which is additional to a standard salary we have, of course, a smaller and less intense spur. One is going to get his standard salary anyhow. If he receives the incentive or bonus in addition, that is all to the good. It appeals most to those who value security, generally speaking, to the older men, with their expenses and status established, who are not so fond of taking a chance sometimes of biting into their regular income in order to get at other times what may be a very great increase.

That need of a certain degree of security can be observed where piece rates exist, and is one of the many causes that results frequently in restriction of output. Not all men like a widely fluctuating weekly income. Not all women, wives and householders, care to have their income fluctuate widely. There is a strong tendency among the men who value security to set their performance at a mark which they can keep up week after week, and not go too far above that mark, at the risk of dropping again.

A similar condition operates where the incentive takes the place of a considerable part of the salary. It is not uncommon, although rather less common than the additional type. Some firms pay hardly more than a retainer as a salary, and have an incentive ranging from one-third up to two-thirds of the man's total income, dependent on the times. That has a very powerful effect, one way or another, sometimes favorable, sometimes not, very largely dependent on the type of man. It should be used, therefore, only where, with that effect in mind, it seems to serve the purpose. It appeals to the chance-takers rather than to the steady sort of person who values security above a chance of considerable gain.

The Steady Incentive. The effect of the steady incentive as against the fluctuating is similar. There is rather a mild effect in the steady incentive. The funniest one I know of is a scheme which guaranteed 15 per cent each year, called itself a profit-sharing scheme and then simply wrote down that each man would get 15 per cent of his wages. Of course after two or three years, the 15 per cent became a definite part of his salary and there was no extra incentive to it at all. A steady incentive does not have to be as steady as that, because after a while it would be written down as part of the regular income and, of course, written off the incentive column entirely in the man's mind. A moderately steady incentive appeals, again, to the lovers of security as against the chance-takers.

The fluctuating incentive obviously is strong. It invites trouble at both extremes—when it is too big and when it is too little. That must be understood in advance of anybody tackling an incentive scheme where fluctuations can be properly expected. If there are no fluctuations then one has to give up some of the strength of the incentive plan. If there are fluctuations one has to expect a certain amount of trouble at certain times, which helps pay for the good he gets at other times. There is obviously an optimum rate and range of fluctuation. There can be too steady a scheme, and there can be one too widely fluctuating for ordinary purposes.

The Known vs. the Unknown. The systematic scheme is the antithesis of the arbitrary. This is similar to a public as against a secret plan. The systematic scheme is usually made known; the arbitrary is always secret.

We must realize that where we have a regular incentive system the assumed virtues or vices of the system itself affect the incentive. The system is known and therefore is subject to the judgment of the recipient. If he does not think it a good system the incentive is not so strong as it would be if he thought it a good system. Any system will be subjected to a variety of abuse—none can be accepted wholly by all recipients. The recipient, at any rate, can be expected to work for his own interest within that system.

The arbitrary scheme, secret in its very nature, induces the recipient to guess at what will be his best course, to guess at what kind of basis is used in the distribution. And if it is supposed, as it would ordinarily be, that it depends upon his superior and the next man up above him and their views, then one can expect the man to work for the good opinion of that superior; which is by no means the same as working to do a good job in his own particular bailiwick. If he supposes that his share depends upon the recommenda-

tion of his superior officer, he will be certain to keep on the right side of that man, if he can, and work consistently to that end, which is not always the same as doing a splendid job in his own corner of the universe.

A secret and arbitrary scheme induces doubts, suspicions and erroneous calculations that must be accepted as part of the price of such a scheme, if adopted. Arbitrary schemes have less harm, at any rate in a small group involving only a few people fairly well known to each other, and the arbiter pretty well known to all. Then the evils of the arbitrary and secret scheme are distinctly minimized. Where there is a very large group the evils ought to be looked into pretty carefully.

Of course, as a matter of practical fact, executives' standards being so difficult to fix, and a system being so difficult to build, an arbitrary scheme is many times the only possible plan. Frequently it is the best one to start with until the outlines of the system shall disclose themselves through experience. In any case, whether it is necessary or a matter of choice, it is important to focus attention upon its peculiar effects.

Large Amounts vs. Small. As to the size of the incentive, it ought to be more widely realized that there is not any simple arithmetic relationship such that twice the incentive has twice the effect. That relation exists perhaps in the middle ranges, but there is distinctly this to be said: that below a certain minimum an incentive can turn into an anti-incentive; above a maximum an incentive can turn into an anti-incentive. Perhaps the latter is not so obvious, but if one sets precise cases before his imagination both truths will be confirmed.

That there is a minimum became clear when we were working out the extension of our partnership plan to our manual workers. One of the questions asked was: What is the least, averaging over a period of years, that will have any effect as an incentive? Obviously if a skilled workman worked hard and enthusiastically all the year and got \$10 worth of non-convertible stock at the end, he would be incited to put a bomb under the plant—not to work harder next year. There is an amount so small that it is best not to have any scheme at all.

The same thing is true of executives. We had in our suggestion plan at one time a \$1 and \$2 award for accepted suggestions. It appeared after a period of years that the one and two dollars seemed so extremely small to the sales department—seemed so petty to men used to getting the larger salaries—that actually it was working against the suggestion scheme. So we changed the scheme and when we could not pay as much as \$5 we paid nothing at all.

There is a sort of Gaussian curve to the amount of incentive: There is a minimum below which it is no incentive whatever and a maximum above which it starts up so many other influences that its effect as an incentive to active and energetic work is smothered. The greatest good per dollar lies in the middle ranges.

Obviously all of these we have talked about are financial incentives and can be supposed to work upon those impulses in a man most readily influenced by money, his actions, his day-to-day intellectual efforts, his planning and scheming. The non-financial incentives, on the other hand, for the most

part influence his attitude, the subtler human emotions of loyalties, feeling of affection, fitness, and all the rest.

That part of the man is, moreover, of great power. We know in war how enormously powerful is the emotional condition of men, how feeling toward the whole thing can give strength that no more tangible motive could ever impart.

Combinations. Dividing up the whole field offers possibilities of clarifying in some way our minds, which tend to be confused by the great variety of schemes necessary to fit the variety of circumstances of one concern or another. We can see through the subject only if we examine it and see it in its separate parts. Any incentive plan of any importance or significance will be a combination of a multiplicity of elements, and we must know something about what those elements can be expected to do if we are to develop a successful scheme.

For example, if we want immediate and marked results we should choose such a combination as an individual, cash, fluctuating (not too heavily), systematic, public incentive of medium size replacing part of salary. That type of scheme would act immediately and act strongly. If, however, the principal objective was the development of an organic unity in the concern—the development of a spirit of team play, of cooperation—then a slower but deeper working plan would be the group incentive—stock additional to salary, fluctuating moderately, systematic and public, with a strong emphasis on the non-financial incentives.

Arbitrary and secret schemes are probably temporary forms which would have little to say for themselves as permanent forms.

It is especially important that an organization, having or considering an incentive plan, should examine its own needs to see whether it wants to stimulate intensive individual action or to cultivate strength of group structure. It should not go into an incentive plan without clearly attempting to find out what it wants that incentive plan to do.

Very naturally, in the rush for incentive plans in the last half-dozen years, there has been much too little examination of what is wanted. Working for one's self alone is easy to stimulate. To work snugly in team with others, supplementing their weaknesses, tolerating their failings, inspiring their best, a man must somehow be led to regard his organization as something a whole lot more than a good milch cow. In the close-knit structures which are likely to win tomorrow it is not so often the lone-wolf brilliancy we pray for, as a ready grasp of the elements of team play, the soberer virtues, not so common, and always of very slow growth.

The strength of the total organization of the team will turn out in the long run to be greater than the strength of a lot of brilliant star performers working each in his own way and each principally for himself. Yet that may not be true in special cases. All I plead for is a critical examination of what it is exactly that the organization wants of an incentive plan before they start in at all.

Of course, these elements that I have tried to set forth affect each other. No living organism can escape the principle of circular response¹ For

¹ See FOLLETT, MARY P., "Creative Experience," pp. 53-77, Longmans, Green and Co.

example, the fluctuation factor, which I have attempted to examine separately, has a greater effect if the fluctuations are in cash rather than in stock. Fluctuations in group incentives have somewhat different effects from fluctuations in individual incentives. In both cases they intensify the incentive, but in each, and especially in the group plan, they bring out some fresh characteristics.

The fluctuating, arbitrary, secret combination has very special dangers, and a fluctuating arbitrary secret and individual scheme has even more serious dangers; in these also the separate elements react upon each other. We are only attempting to separate them in order to see a little more clearly into the whole complex subject.

Finally, no thoughtful concern should ever leave an incentive scheme alone to work by itself, although some thoughtful concerns have, I confess, done so. At any rate they should not in the future. The scheme, whatever it is, is influenced in its effects by the attitude of sincerity, of faith, of confidence, which builds itself up around it; by the freedom and effectiveness with which any current facts pertinent to its working are made known. Any management must realize that an incentive scheme affects those in the organization who are not included in it; and in its turn the scheme itself is affected by the attitude of the excluded toward it. One cannot escape that. A scheme, particularly one in which there is only a very small group of men sharing in the incentives, must be weighed as to its value against the anti-incentive that is upon those not included, who must let down somewhat in their efforts when made conscious of their exclusion day after day by seeing the chosen group of people whom they know to be included. The effect upon the excluded is one to be counted by management in considering incentive schemes.

New Plans vs. Old. It is true, too, that any plan is different in its effects when new than when repetition and familiarity have been at work, for better in some cases, for worse in others. In a complete audit of the value of an incentive scheme, not merely this year but the years of the next decade must be made to render their accounts. The early eagerness to make a showing may turn to satiety or conservative fear. In some stock incentive plans this conservatism must be definitely guarded against.

In discussions of incentive schemes today, while the subject is new, there is stronger enthusiasm for their effects than a cool social psychologist could possibly justify. But that is partly the effect of the idea itself and partly the effect of its newness. A new scheme, put in as against nothing at all, is more effective while it is new than it is as it grows older. That, of course, is in accord with human nature. The repetition, year after year, is in itself a definite part of a scheme and has to be counted as such. It can be made to work for good; it can be made to work for evil. My only claim is that it must be recognized.

We have noticed in our own case decided differences in the effect of our plan in the early years and later; and a similar difference in its present effect upon men who have been in from the start and accumulated a fairly considerable amount of stock as against those who are just in a year or two and are beginning their accumulations. Upon men who have had the possibility of sharing presented to them year after year, and with whom it has become

fairly habitual to think that their efforts will finally result in value to themselves and to the group they are working with and upon men on the other hand, who see it for the first time, the difference in effect is decidedly striking.

Schemes of companies must be gauged to the run-of-mine men. No two men are exactly alike. Anybody dealing with incentive schemes or any other scheme having to do with management must realize that odd sticks in human-kind must be expected, and somehow or other handled. But the plan itself must be calculated not for these special folks, whether they be particularly favorable or otherwise, but must be calculated to work upon the great middle section—85 per cent of mankind. Too often I have heard a scheme argued for or against on account of the effects on one man who went up to the boss and said this or the other. Sometimes he was boot licking the old man, telling him how wonderful he was. That is a danger our judgments undergo—especially in executive plans—that we often hear from Jones or Johnson how it affects him. But we won't necessarily discover how it really affects him by listening to what he has to say about it. Our judgment must be based upon the group as a whole and not upon the persons who come up and talk about it, pleasantly or otherwise.

Non-financial Incentives. There remains, after all the financial incentives have been worked out, the more powerful, the larger, and much more difficult field of the non-financial incentives. They range from a quite intangible company tradition through a hope of promotion, an atmosphere of emulation, a spirit of the team, conditions which allow of a proper pride in one's work, fondness for one's boss, special distinctions of title or privileges of position; through the powerful social incentive of satisfaction in belonging to the group, so effective, for example, in the teaching profession; finally, to the high professional appeal so astonishingly developed by the telephone company and apparently, in their case, without a special subsidy or bonus scheme.

All these, and plenty more are incentives of a cogency not to be denied which pull upon those powers of a man that financial incentives cannot reach. Try to buy patriotism, not of the audible but the honest sort. Try to buy the power to stand at Verdun. Is it not significant that armies depending upon financial incentives—that is, mercenaries—have long since failed as any significant sort of military organization?

In work, the results of which are very difficult or for the moment impossible to measure, an individual financial incentive may easily do as much harm as good. In executive work and in selling, just as much as at the bench, there are penalties often hidden for years in setting incentive rates in advance of a thorough job analysis and control of job conditions. The old lesson of the factory is not to be lost sight of—piece rates set on guesswork gave us immediate results that fooled us completely; things were often so bad before the piece rate was made that an immediate improvement was a cinch. Then, very slowly and gradually, and in hidden ways, year after year, the evils of that guessed-at piece rate began to develop and sometimes we went through a type of hell to get rid of them, and sometimes we did not even succeed in getting rid of them at all.

Very much the same is true, on a wider scale than anybody appreciates, of salesmen's commissions that have set themselves—the greater good of which was probably accomplished at the beginning. The greater evils have been accomplishing themselves ever since. We know now that we cannot expect all machinists to discover the best ways of doing their work just by giving them a piece rate. It is to no degree more probable that the salesman or executive will discover his best way under a like spur. Where conditions are not under control it is notorious that individual incentive rates result in many injustices.

One of our section chiefs put the matter rather concisely in our forum. He said: "What our work on setting standards and incentives for office workers did strikingly, was to set forth the best use that could be made of their time." It was one of the principal benefits. It made clear what was the best use that could be made of their time. "What the supervisors lack," he said, "is a like knowledge of how they actually are using their own time and how better to use it." Not one man in a thousand, I suppose, could carry on a job and at the same time observe how he is and how he should be carrying it on.

The same thing is true of all our executive jobs. One of the best things we can do is to have a round-up job analysis of exactly what executives are doing and how they are doing it. Without going too finely into it, to set the beginnings of some kind of objective view, objective standard, is in itself a powerful incentive. An extremely strong part of the incentive idea all around lies in the concentration, the reorientation, and the refocusing of attention that any critical and objective examination of the job induces. And there are a number of cases to prove that where the analysis is too uncertain, where the standards are too varying and uncertain to allow the fixing of incentive pay, strikingly good results have been obtained by merely making the rough standards known.

We had a good example of that inside the shop where we worked hard to set an incentive pay for guillotine cutters, and had to give it up. But merely making the standards known to the workers resulted in something like a 30 per cent increase in production. So even the roughest sort of preliminary analysis may work out and may often work more successfully without an attempted financial incentive than with one.

Thus we reach the fact that one of the best incentives for both immediate and long-time results is high-grade management. The manager who knows what his crew should do, who can teach them how best to do it, who knows currently how nearly they are living up to sound standards, is in himself an incentive of no mean order.

It is certain, of course, if adequate management is absent, that all other sorts of incentives lose largely in their good effects and many may turn bad. A good incentive plan under bad management is likely to have bad results.

Far from being any substitute for good management incentive plans make great demands upon management. Carefully thought out and well supported by management, incentive plans may lead on into high non-financial as well as financial successes.

PRINCIPLES OF INCENTIVES FOR EXECUTIVES AND KEY MEN

By J. P. JORDAN, *Partner, Stevenson, Jordan & Harrison*

Times change. Men change. Mental processes change. Changes of all sorts are constantly going on. Interest which we take in a certain subject today shifts to another tomorrow. A feeling of intense interest in our job today changes to a feeling of "what's the use" tomorrow when the controlling stockholders announce a sale to or merger with another company.

It's in the air to be nervous about our work, our jobs, our families, our future. The larger the company, the further down we are from the top, the less our feelings of security; the more we feel our entire dependence on the whims or the schemes of the big bosses, never knowing whether there is such a thing as permanency of job, policy or even continuity of the business as is.

Most of our nervous reactions are imagined. They are but the reflection of things in general. But the nervousness is there just the same; and, psychologically speaking, our performance is restricted; our initiative checked; our happiness clouded; and our real value lowered.

The writer's work brings him in contact with many organizations. Let the slightest rumor of a change in management, a merger, a sale of the company or any other thing of like nature occur and such thoughts immediately become uppermost. They absorb the time and thought which belong to productive effort. Conversation is largely concerning the rumors. In other words, the actual observation of the writer in a number of cases has shown a heavy percentage of the time of the best men of certain organizations wasted in speculation, discussion and worry as what was going to happen or what might happen.

In the great majority of cases this interruption of productive thought and effort came about through a sort of inferiority complex arising from the realization that after all, most men concerned were purely *employees*—on a salary, differing only from subordinates in the size of salary. The size of salary itself aggravated such a situation because a new broom would always aim at the big salaries when it thought it had a spectacular job to do in trying to justify a merger.

Therefore, industry and commerce has a problem on its hands, not only to make a consistent and satisfactory net profit, but, in order to increase and stabilize this net profit, so to give heed to the psychological call that every means be resorted to in order to safeguard the mental attitude of the personnel of the organization against fear, nervousness, worry or any other harmful mental reaction.

Incentive methods for key men and executives provide a very effective safeguard against the detrimental factors just described and besides, they increase profits. There is no doubt about that.

We shall deal with this subject under certain definite headings.

Conditions as to Organization and Procedures. To provide proper incentive methods, there must exist certain conditions:

1. *Leadership.* There must be a leader heading the organization who *believes* in men, *makes* men and then *leads* men to do big things.

2. *Definite Responsibilities.* There must be a definite plan of organization, clear definition of duties and in all ways a clean cut organized procedure.

3. *Knowledge as to Operations.* There must be adequate records to back up all responsibilities—and no more.

4. *Marks to Shoot at.* There must be standards to meet and beat. This means a setting up of what *must* be done to make a normal result.

5. *Extra Remuneration for Beating the Normal.* This is the subject of this discussion—an incentive plan whereby extra remuneration comes automatically for results which beat the normal.

Let us assume we have the first four items in fine shape. We may now proceed with the matter of incentives.

The Necessity for Incentive Methods. Business today requires thought and action far beyond what has been the normal of past years. Competition in staple lines, competition in improving lines which depend on design or quality, competition in lines where style changes and fickle fancies dictate, competition between volume seekers and all other kinds of competition require a concentration of effort, judgment, and skill in all the functions which make up a business of any kind which must be far more effective than any such effort in the past.

Capital is impotent beyond furnishing the plants, materials, labor, and all the other elements which may be bought. But the skill necessary to design, fabricate and sell products at a profit must come from the organization. This organization is made up of human beings, some more and some less skilled in their several scopes of ability, but each one human and subject to the same emotions.

A common human trait is to settle into routine—physically and mentally. The great majority of human beings become fixed in habits of thought and action, a natural thing when we consider that most of us in early life come up through more or less routine work where only those who fight it off through study, reading, and dreaming of bigger things succeed in breaking the spell, emerging into broader and more effective lives.

Then as we get more settled, home responsibilities, outside interests of various kinds, real or imagined physical troubles and all other conceivable things influence us to regard our jobs as the wage or salary source, looking for all the raises the traffic will bear and thinking ourselves fixed for life, resulting in a type of service which may be normal but is far from what is necessary today. Length of service unconsciously builds up such cases as just described. Mortgages on jobs become numerous in the minds of the majority. This class of mentalities is found in all grades throughout an organization from the bottom clear to the top and the pity is that such conditions exist, but they do. The cure? Not wholly—but substantially—incentives for efforts and action *beyond* this normal.

It will be said, such conditions as just described do not exist among key men and executives. But they do, and sometimes to a worse degree than among the lower grades. In any event, the unused latent ability in every key man and executive, according to many authorities, is as great as that which is used. That is, the percentage of effectiveness of the great majority of key men and executives is, on a normal basis, not over 50 per cent—

probably less. This statement will undoubtedly be disputed and there is but one way to prove it to the satisfaction of each individual.

Did you ever actually study your own time, the uses you make of it, the accomplishments you produce and the real yield which comes from the brain effort you exert and the time you actually spend? Can you not remember right at this moment how many good germs of ideas have floated around in your imagination that never have been incubated into a valuable plan? Can you not name right now a whole array of things you would like to work out but that you think you have not had time for? Will you not without further thought admit that many such germs of imagination of actual ideas might have been put up to someone to work out long ago? Could you not, if you had enough such ideas, have very profitably hired even a new individual to follow through on a lot of them?

In other words, how many of us would admit that we are perfect or anywhere near it? How many of us dare even to think that we approach the best there is in us? How many of us feel that any of our associates or subordinates are themselves anywhere near the point of perfect use of brain and physical capacity and ability? But granting all this, who can be perfect or can anywhere near approach 100 per cent? Admittedly, no one. But a 50 per cent increase in yield from brain power on a 50 per cent existing effectiveness still means an allowance of 25 per cent for ineffectiveness, and this increase of 50 per cent of existing effectiveness means wonders.

Only three things actually spur any of us on to real accomplishments. First, the joy and satisfaction of accomplishment; second, the fear of results if we do not accomplish, and third, a direct financial interest in the results of our accomplishments. Now, combine the joy of accomplishment with the joy of increased income from greater accomplishment, and we find a combination of tremendous power. Even the increased remuneration from better accomplishment without the joy is sufficient to produce great results, as in most cases, those who lack the joy of accomplishment want more earnings to be able to have whatever they do take joy in.

Salaried men as a class lack the spirit of proprietorship which in itself is a most powerful driving force. Such salaried men in key or executive positions are transformed when they are put in a position where, on measured performances, they automatically share in the savings from better performance or in the increased profits which result, or both. Any man who says he is doing all he can possibly do is absolutely wrong. Not one of us can truthfully say that. Any man who can truthfully say that he would or could do *no more* under an incentive plan than he does now on a salary has no remote idea of the psychological result of incentive stimulation.

It might be mentioned here that incentive plans should never take the place of or affect salaries in any way. A salary should be paid everyone to an extent commensurate with the position which the company wishes each individual to hold in the community or business world, where every reasonable item of living expense is covered in order that there may be no worry or mental interference with effective work.

For this salary normal effort is expected. This normal effort equals the normal return to stockholders allowed on the net value of capital invested.

Then, through a combination of profit sharing and savings sharing, the key men share results better than normal with the stockholders.

Incentive remuneration taps the hitherto unused forces. It brings into the picture a sporting instinct which lies dormant when on a straight salary. It stimulates imagination; it promotes more profitable use of time; it increases the feeling of responsibility; it opens visions of a better home and more for the family; it leads to dreams of a family more generously provided for when left alone; it makes men out of morons, and bigger men out of big men. Why? Because everyone feels, "this is my business"; and when anyone feels that his job is his own personal business, that the results are his to accomplish and that a better accomplishment means greater income, a psychological force is set into operation which is one of exceeding power.

Profit Sharing, Its Advantages and Disadvantages. For the highest executives, those who are responsible for the overall results of a company, profit sharing alone is indicated and is of the greatest advantage.

For those junior executives, major department heads and others who must work in a closely coordinated manner, it is of great advantage for a portion of their incentive to arise from a share in profits. But only a portion, as they also should derive their incentive earnings from the results of their own particular responsibilities.

Key men below the junior executives and department heads just described should derive their incentives entirely from the results of their own responsibilities. With this class, profit sharing has not only no advantage, but it is, in fact, a very disadvantageous method.

It may be taken for a fair rule that when any responsibility is largely centered in an activity which is but partly contributory to the result as a whole, the incentive plan should recognize that fact and be so arranged that it deals only with those factors covered by each such responsibility. We may draw illustrations for this statement from such activities as all the line-and-staff departments including selling, manufacturing, engineering (meaning all designing and such work) accounting, purchasing, traffic, and so on, with all the subdivisions of each.

For instance, what does it mean to a sales division on the Pacific Coast in terms of ability to be at all responsible whether the company as a whole makes a profit or a loss? But it does mean something as to whether or not they sell a satisfactory quota at an allowed expense or better. A foreman of a self-contained department in the plant hardly knows how to spell the word profit. But he does know what goes on in his department and if a standard performance is set up for him to beat he can go at it with full knowledge and authority. To him, overall profits as a basis for bonus is worse than nothing, as, if he cuts his cost and the company makes no profit, he gets nothing. The psychology of such a result is disastrous.

Therefore, profit sharing is advantageous with high executives, and partly with the next lower grade. Below this grade, it not only is disadvantageous but is positively dangerous. Besides the fact that the higher executives should stand or fall on the net overall results, they and some of lower grade need the effect of standing on overall profits for the benefit of stimulating cooperation between departments. A common purpose is therefore set

up, and it helps to level down the barriers between departments and foster a real company spirit.

Setting Up a Profit-sharing Fund. It might be well to state, while on the subject of profit sharing, that the setting up of a profit-sharing fund is quite simple, although two or three points are usually debated to a considerable extent. First, the value of the net assets must be arrived at. Second, there must be fixed a percentage of the net assets to be set aside for the stockholders as their normal return. These percentages usually run at 6 or 7 per cent except in very special cases.

Next comes the percentage of profits remaining after the stockholders' exemption is deducted, which will form the bonus fund. The writer believes in an ascending percentage, starting fairly low and increasing to a reasonable extent as the profits increase. This method seems far better than a flat percentage, and certainly a decreasing percentage is the height of folly. But boards of directors often balk at the ascending percentage, as they claim that the profits themselves increase, thus automatically giving a larger bonus fund. But, who increases these profits? Capital? No—as capital is inert. Management? Yes—as management, including top executives and all key men, are the ones who do the job. As profits grow larger as a result of greater and greater effort, should not the key men and executives who do the job profit to a greater and greater extent, even to an extent greater than just a flat rate proportion of an increasing profit? The psychology of it is wonderful. It means greater and greater bonuses for the key men; and, as the stockholders always get the lion's share, they too profit to a greater extent, as do the men themselves.

Savings Sharing. Savings sharing does not mean just saving money. It may mean spending more money. It does mean spending less money per resultant performance. That is, if \$1,000 is supposed to design, or manufacture, or sell 1,000 units of performance, and 1,300 units of performance results at a cost of \$1,100, a "saving" of \$200 is made. Or, if 1,000 units of performance result for a cost of \$900 a saving of \$100 is made.

A standard or bogey, or whatever you like to call it, is set up for each measurable unit of every department. Actual performance is measured by the standard, and a saving or loss results. This we shall regard as sufficient to describe savings sharing for the purposes of this paper, as it is not the intention to submit herewith a definite set of specifications for installing such a method.

Savings sharing is superior to profit sharing in that it is applied directly to each definite division which is measurable. What the overall profit may be means nothing to most key men below the chief executives. Even if it did mean anything, what can they do about it other than operate their own departments in a manner to beat their own standards and in that manner, and also in their own bailiwick, contribute their share to the general result?

To accomplish improvement, the measurement, control, responsibility for and participation in the final results of all operations should be tied just as closely as possible to the point where the actual doing of things takes place. The selling district on the Pacific Coast is a responsible and meas-

urable activity. So is every other sales district. So is every department in the plant, direct and indirect. And also the engineering, purchasing, accounting, personnel, and all other departments. Thus, by tying our incentive plan just as closely as possible to each separate responsibility, gauging results to a fixed performance which must be reached before bonus takes effect, we stimulate all kinds of action where each group may produce results irrespective of other groups or the whole.

Maintenance, stores, shipping, tool room, power, and all such indirect departments in the plant can be measured in such a manner as to provide an incentive plan which safeguards the company and promotes extensive savings. Over a given time the ratio of all such indirect costs must be maintained in a manner to assure profits. Incentive methods practically insure such proper ratios.

Engineering effort, covering betterment of product, current interpretation of customers' orders and all other elements of the engineering function must be kept in ratio to a certain fixed portion of the sales dollar. Bettering this ratio brings a bonus.

Sales effort, controlled by quotas of sales at allowed budgets of expense, with a further check as to the margin of gross profit secured, brings in an incentive plan which has every possibility of increased sales at a lower unit cost. Group incentive plans for segregated sales divisions eliminate the old bugaboo of who gets credit for individual sales, and makes possible a cooperative sales effort which is healthy and effective.

Bonuses in all departments may be paid monthly, quarterly or annually. When possible, monthly payments are to be preferred. In companies where more or less violent swings take place in volume, the bonus month may be one-twelfth of the last twelve months, thereby leveling the swings.

Bonuses earned may best be distributed on a point rating for the men who participate. For instance, the head of each department will be rated at 100 points. The next best may be 80 per cent as good and be rated at 80 points, and so on. The total of these points divided into the bonus fund earned gives the value per point, which, multiplied by the number of points assigned each individual, gives the amount of bonus for each.

Only half this amount should be paid in cash. The other half goes to a reserve fund to be retained until the end of the year, against which any losses will be charged. At the end of the year the reserve fund of each major department is distributed on a point basis where each participant in the departmental funds is rated on a basis of the comparative value of each to all the participants as a whole throughout the department. This promotes an overall cooperation, as it eliminates undue competition between departmental subdivisions.

Therefore, with quotas and budgets set for each division of each department, an equitable distribution scheme set up where bonuses earned are shared by individuals in ratio to their contribution to bettered results, we create a psychological force which is very powerful. We fix a responsibility, set a mark to beat and share with those responsible the results which better the mark. Such a scheme brings to each key man a personal sense of pro-

prietorship. It makes men. It brings out latent abilities which otherwise would lie dormant. It increases profits.

Combination of Profit and Savings Sharing. In certain cases, a combination of profit and savings sharing should be used. As has been stated before, the highest officials should stand or fall on profit sharing. But others may well participate partly in profit sharing and partly in savings sharing. In order to illustrate this point, let us assume a large company where there may be a president, and at least a vice president in charge of distribution and another in charge of production. Under the vice president in charge of distribution may be a general sales manager and other key men. Under the vice president in charge of production may be a general works manager and other key men. The president and vice presidents should be in profit sharing only. The general sales manager and the general works manager may better receive, say, one-third of their bonus from profit sharing and two-thirds from the results of their several departmental activities on the savings sharing plan.

The effect of such a method is obvious. It softens the partiality for departmental prerogatives and brings in the overall profit feature. It insures cooperation between departments, but at the same time stimulates the efforts to cut down departmental costs and increase departmental performance.

Interminable combinations of this nature can be worked out and must be worked out, as no two concerns have like relationships between their several departments. Therefore, each separate concern must work out its own combination.

The point to be brought out is, therefore, that with some participants, both profit sharing and savings sharing should be used. Such a combination means the preservation of cooperation while at the same time hammering down departmental ratios of cost.

Publicity of Methods. Now we reach the ground of endless debate. The questions are: first, should the exact method of computing bonus funds be known by the participants and second, should the exact basis of distribution of bonus funds be known also?

The answer will be given as YES in capital letters. First, let us consider the matter of bonus computation.

What advantage can there possibly be in secret figures as against the decided advantages to be obtained by working in the light? Savings sharing plans involve two main factors: first, the bogey to beat and the fund to arise when the bogey is beaten; second, the distribution of this fund. The setting of bogies, that is, the quotas of performance and the cost of these performances must be done *with* and to a considerable extent *by* the interested responsible key men. Then, as the game progresses, the actual performance placed against these bogies tells the story of success or failure. It posts the score of the great game, and the psychological effect of just this procedure is exactly what we want. Without it, no incentive plan has any force. Therefore, as the great force of incentives lies in a complete knowledge of what to beat and whether or not it is being beaten, there seems no doubt about the advisability of publicity.

But, it will be asked, why let them know what percentage of the savings will be set aside for a bonus fund? Because that is part of the game. It is the ultimate goal to reach, and therefore must be known. Besides, the withholding of such an important part of the scheme from the knowledge of the men suggests "cagey" dealing. It suggests a type of trading that has no place in square dealing.

The distribution of the bonus is another matter. Here we run into the old habits of secrecy regarding salaries. As to secret salaries, there always comes up the thought that someone is ashamed of something. *If salaries are set fairly and squarely, with good reason and sound premises, why keep them so secret?* If A gets \$10,000 and B \$8,000, and B ever finds it out, he may be peeved because he can say nothing. But if the chief said "B, you are getting \$8,000 while A is getting \$10,000 for such and such reasons," B could see why and work his head off to overcome his shortcomings.

So it is with point ratings for bonus distribution. The head of a department will get 100 points—let us call him A. B gets 80 points, C gets 60 and D gets 20. These points are set on the best possible judgment of A and his superior. B may get less salary than C and yet be more effective. This may often happen when C is older, has served many years and therefore has been raised in salary while B is a new man who has not yet reached the salary level of C. Admittedly C may be getting too much salary for his present job; but we all know that red-blooded companies are not trimming salaries in such cases of older employees. Yet B should get more of the bonus, as he is contributing more toward the savings worked out.

Why conceal such things? Why not have B and C know the exact truth? In fact, absolute knowledge of where one stands is in itself a powerful incentive to do more and better.

Different positions carry with them different types of men, and both the positions and the men may have a different angle on the matter of making savings or increasing profits. A treasurership requires a certain type of man—honest, steady and 100 per cent trustworthy. He need not, however, be a type such as a controller who is, or should be a very powerful element in profit increasing movement. On the theory that every man should have a salary commensurate with how the company desires him to live without worry or care, these two men may receive the same salary. But the controller should receive a greater share of savings or profits on account of the nature of his job and the man required.

It seems that there is every argument for publicity of all that enters into an incentive plan, both as to how bonus funds arise and the distribution thereof. Frankness promotes confidence; and after all, it's the whole "gang" working to the same end that brings the big results. No group can work to the same end without a clear knowledge of every element of the problem.

Bonuses and Company Stock or Any Other Specific Use of Bonus. If an individual has a responsibility placed upon him, has a definite goal to meet and beat, organizes his work effectively and beats this goal to the extent that a substantial bonus is earned, what then? Must he take any kind of forced feeding in respect to what he receives as a bonus?

The question is often asked as to the tying in of company stock with bonus plans. That is, should bonuses be payable wholly or in part in the stock of the company? Of course, the theory of that is to tie in each employee whereby he is a stockholder as well as a responsible key man.

Other than the matter of company stock, there also is the question as to whether or not any company should, in any manner, concern itself with what the key men and executives do with their bonus. That is, should any company attempt to be paternalistic in respect to the personal investments of the men who are operating the affairs of the company?

As to the stock feature, no two companies are alike. Some stocks are good; some are not. In some concerns where there has been stock manipulation, the water is dripping freely. In others the stock is sound and high in its intrinsic value. In some companies there is good backing for the stock on the market and in others none. Some stocks are listed on some exchange where there may be ready sale, and others not. Close corporations, where stock is held by families or groups and there is only the good nature of the group behind the stock present another situation. Some companies are old and their stock issues are quite fixed. Some are new and their stock issues may hit the public fancy. Companies in certain staple industries may present little chance of stock appreciation. Other companies may be in the class best illustrated by what General Motors was during its rise—a new industry with new developments by a new school of progressive management.

As to any other thrift, investment or other savings schemes, there is doubtless much to be said as to the need for busy men to have an avenue for counsel, at least, if desired, if not an actual means of investing whatever portion of their extra earnings they so desire. The 1929 break in the stock market is a shining example of the risks run by individuals in market operations. In fact, the movement of the present day as is evidenced by so-called living trusts, mingled trusts, and all such plans is along sound lines well worth the consideration of each one of us.

But the question is, to what extent should any company embody any plan whatever, particularly investment in its own stock, as to the disposition of bonuses earned in the incentive plan which it operates. Should there be even the slightest suggestion of pressure on the recipients of bonuses as to how they either receive their bonuses or how they shall use them after receiving them?

It seems quite reasonable to conclude that when men have expended supereffort in their work, have made records of accomplishment that have never been made before, have increased the profits of the company, and in all ways have "come through," the enjoyment of their extra remuneration should be protected from any paternalistic influence whatever. Even any advisory or honestly planned help should be conducted in a manner to guard absolutely against any feeling on the part of men that they are not playing the game if they do not choose to participate.

From the writer's personal experience he has known many exceedingly capable men who have been faithful, hard, and even zealous workers. They have reared families which are credits to even Rooseveltian ideas. But in doing this, the pocketbook has been strained to the limit to keep abreast

of all the expense incurred. There are no luxuries in such families. Then comes participation in a bonus. With regular salary budgeted to the limit for house and school expenses as has been the case for years, is it not a fact that the acquisition of something outside the strict line of necessities will usually produce a psychological reaction which will spur such men on to greater effort? In other words, "all work and no play makes Jack a dull boy." Therefore, a little relief from the round of absolute necessities makes life rosier, opens new and broader thoughts, and dislodges the mental cobwebs. This reaction, in turn, produces better effort, which brings more savings and more bonus.

After the craving for relief from the drudgery of working for necessities only has been appeased, then is the time to paint the picture of investments and provision for the future of these very families. But remember at all times that whatever a man earns by his wits and his efforts is *his*. While any company may well provide optional schemes whereby the future of its key men may be safeguarded, these schemes should be sold and not forced.

As for tying in key men, can any tie be stronger than a properly devised and carried out scheme whereby each one may profit by his own supereffort in accordance with a formula which safeguards the *company first* and then throws open the door for every key man to make what he will?

Conclusions. The intent has been to sell the idea of key men and executive incentives as what seems to be the greatest thing that has been taken up by management in years. No attempt has been made to tell how to work out such plans. Obviously that could not be done. Furthermore, it is useless to discuss how to work out any plans at all when the basic thoughts in respect to the major features of such plans are in a state of fog, a condition which may confidently be stated as the situation today. However, that is a normal condition, as every new development must necessarily go through its steps of evolution.

Conclusions suggested by the writer as a result of his own reasonings, at least, in respect to key men and executive incentives are:

1. Incentive methods are necessary to bring out supereffort and create a definite feeling of real proprietorship.
2. The preeminent forerunner of any kind of incentive plan is real, unalloyed, and effective leadership.
3. There must be a definite plan of organization with authorities clearly fixed and specified.
4. There must be adequate records to match the various responsibilities.
5. There must be standards of performance for every move in every department.
6. There must be a profit-sharing scheme which provides for a normal return to stockholders for their net invested capital, with a specified percentage of remainder profits to form a profit-sharing fund.
7. The percentage of remainder profits may best be a sliding percentage, increasing in size as profits increase.
8. Highest executives derive their entire incentives from the share of profits set aside as a bonus fund.

9. Executives just under highest should derive their incentives partly from the overall profits and partly from the "savings" in their own departmental activities.

10. All key men other than those mentioned should derive their incentives from bonus funds created by setting aside a portion of savings made by bettering fixed performances.

11. Savings as regarded in this discussion means the betterment of the relative performance of units of results produced to allowed expense for so doing. It does not mean simply absolute savings of money.

12. Distribution of incentive funds should be on a rating of effectiveness in current results, and not be entirely or even partly, sometimes, in ratio to salaries.

13. Everyone should have an adequate salary entirely without regard to any incentive plan.

14. The manner of setting up all funds, profit sharing, and savings sharing should be known to the participants.

15. The rating of each participant in each fund should be known to the other participants.

16. Only half of the bonus earned should be paid in cash during a calendar year, the balance going to a reserve fund against which all losses shall be charged and distributed at close of year to all participants on the basis of their value one to another in the department as a whole.

17. The rating of all participants as to their value to the organization as a whole, the basis on which the annual reserve is distributed, insures a team work between departmental subdivisions.

18. Except in very outstanding cases, any forced investment in or distribution of company stock as a bonus is to be avoided.

19. Bonuses should be paid to everyone with no paternalistic string attached thereto—or even a suggestion of such a thing.

20. A company may provide optional investment plans for its men if such are not impressed as an expected route for everyone to follow.

21. The whole secret of an incentive plan lies in its psychological effect.

With this twenty-first conclusion, let us close the case. As has been previously stated, any business where men are on salaries only, requires more than a normal employee spirit. To succeed today in maintaining even normal profits, intense attention and effort is necessary.

To make profits greater than normal, a supereffort is necessary. Super-effort must be induced by supertreatment for the key men involved—and why not? War medals are awarded for performance *beyond* that normally expected of a soldier. So it is with incentives. A salary should be paid giving adequate return for normal service and normal results. Such performance should be definitely set up in the form of quotas, budgets and standards of all sorts.

Then, when these normal results are exceeded, every key man and executive should automatically—not paternalistically—receive his reward. Such procedure intensifies responsibility, stimulates effort, makes big men bigger and rolls up a net profit which otherwise would be unknown.

CHAPTER VI

EXECUTIVE LEADERSHIP

BY ORDWAY TEAD, *Editor of Business Books, Harper & Brothers; Lecturer in Personnel Administration, Columbia University*

It is the purpose of this section to discuss the relation of executive work to the task of leadership; to clarify a conception of leadership which is sound psychologically; to consider how leadership in economic life can be cultivated both in amount and quality; in a word to consider the hows and whys of the technique of executive leadership.

The Nature of Executive Work. The way in which executive and directive work is viewed both by those who practice it and by those interested in building up a science of management, has been changing in recent years. Notions of absolute managerial authority, strict and unquestioning employee obedience, arbitrary imposing of managerial fiat—the whole older military idea of the relation of the commander to those commanded—these are being superceded, and for various reasons. In the first place, this kind of relationship is found not to work well in a democratic community. It does not work well because people are today less disposed to be governed by their fears than by their desires; because they know better what they want and how to get it; because they have been taught self-respect and ideas of equality. A spirit is abroad in the modern world which makes bossism increasingly offensive to those who are bossed.

A second reason is that the influence of modern psychology on managerial thinking has increasingly helped to show that leading and not bossing, training and not scolding, inspiring and not threatening are the sounder ways to appeal to human nature.

It should therefore be possible—and there is experience to prove that it is—to help the managerial personnel of business and industry to work consciously to throw off the older notions of bossism and to cultivate another and more effective attitude toward directive relations—one which is in harmony with these undercurrents of popular sentiment in the present world and with the best finding of modern psychology about the nature of people and the way in which they are summoned into action.

Power Resides in the Function, Not in the Person. But first, certain introductory observations should be made as to the true character of executive or directive work. There are directive positions and functions in all organizations. The director of men—be he factory manager, department head, foreman, department store buyer, or office manager—directs primarily by virtue of his position and not of his person.¹ The directing and leading

¹ "Scientific Management in American Industry," Taylor Society.

responsibilities inhere in the job or function. The total situation in which director and directed find themselves has this impersonal aspect. And it is important to the building up of a healthy notion of leadership that this idea of the inherent and functional nature of direction—as contrasted with its personal aspects—be kept in mind. Personal supervision of others is not a height achieved by a few born leaders. It is an inevitably and widely experienced part of the whole managerial job. And the director who thinks his power over others resides fundamentally in his person rather than in his function does not approach his work with a sound mental attitude. He is in danger of claiming too much for himself and of demanding too much of others. He is in danger of being too egotistic, too arbitrary, too proud of his place and his powers.

Indeed, because his position carries directive functions implicitly in it, the "orders" that he has to give should be at a minimum. Most of the routine "instructions" as to work should not have to be orders at all, should be the natural explanation and overseeing of individual responsibilities all down the line, should call for help in facilitating performance rather than for commands of a bossing character. If a working group is as well organized in its relations as good scientific management entails, the directive problem should in reality take on leadership attributes as its major characteristic.

One special reason why it is useful to emphasize this important point at the outset is that in business the director of men is not usually selected by those he directs. A group of workers finds someone "over" them to whom they are expected to look not only for "orders" but for inspiration to partake in common efforts for an objective which certainly at the outset they do not have too clearly in mind and for which their support should be consciously secured. In some other forms of human organized activity the directing head is, at least supposedly, the chosen from among his constituency. This fact gives real force to his ability to know what they desire and to his ability to summon everyone to devoted following of the group's objectives. The group-appointed leader would seem to have—at least in certain fields—a psychological advantage in rallying his following for achievement. He leads because leadership is expected and desired of him. This advantage is scarcely present in industry as yet; and therefore the directive head must be at pains to overcome the subtle mental resistance which may well arise between a force and the manager who is not selected by them and is not responsible to them.

Another way in which this characteristic of leadership has been stated is to say that leadership is a function of the relationship, not a personal right. This is not the only or final word on its nature. But it is a conception which introduces a helpful corrective to a too highly personalized view and which is a helpful stimulus to the systematic cultivation of leadership qualities among the thousands who must perforce exercise leadership functions.

THE NATURE OF LEADERSHIP

Just as the conception of executive work is changing, so also the conception of leadership is broadening. There are, of course, different kinds of leader-

ship. But we are here concerned with executive leadership as that is manifested in business organizations both in face-to-face relations of rank and file and foreman, of foremen and superintendents, of superintendents and their company heads, and secondly as it appears between the top executive officers and the whole organization in leading them to the adoption, interpretation and execution of corporate policies.

In the face-to-face type of leadership the personal characteristics of the leader of course assume greater relative importance. In the latter type the elements of intellectual planning and managerial imagination are more needed and come prior to the necessary personal contacts implied in conveying new corporate plans and purposes to the membership and in the detailed supervision of carrying them out.

One aspect of the nature of leadership disclosed by a wide examination of leaders in action reveals the common factor of the pleasure and satisfaction found by those led in following the leader. Fundamentally in all human affairs, political, military, religious, etc., the leader is summoning those who are able to find their own good in the aims the leader holds and works for. The loyalty displayed by the led may often have been mistaken. There have been false leaders with trivial or stupid aims. The elements of personal "magnetism" or domineering personality may have been too much in the ascendant. But fundamentally the people had to be served. They follow where they think it is worth their while to be led. There are, indeed, these two phases always closely interwoven. The leader is to a certain extent opening up new visions of what will appear as good and worthwhile from the point of view of his constituents. And he is also, if he is successful, voicing and making articulate those objectives of which the led have but have not yet become clearly aware. The good leader in the larger sense is both a seer and a mouthpiece.

Newer View of Leadership. One difference between the older and the newer view of leadership centers about the point as to what parts of people's natures are being appealed to by the leader. Here is where the modern conception of human nature has wrought an important change. It says that the positive and not the negative elements of human nature are the stronger ones—hope rather than fear, self-assertion rather than submissiveness, constructiveness rather than destructiveness, love rather than hate, security rather than uncertainty, growth rather than stultification. It is the creative, emerging, developmental quality of human nature which is now realized to be the more dominant, the more permanent, the sounder element in personality to build upon, and which therefore must be appealed to in summoning people to action.

Hence modern leadership is to be defined¹ as the ability derived from that combination of qualities by means of which one gets other people to work with him toward some goal because they find that they want to help him to realize it. Both together find the effort toward their common objective satisfying. As desire has been said to be "the soul of will," so also is it the soul of leader-

¹ See TEAD, ORDWAY, "Human Nature and Management," Chap. XII, where leadership is defined more exhaustively in relation to economic affairs.

ship. The leader today is he who gets things done because the led come to want to do it. He establishes a creative relationship in which desires become integrated or harmonized by efforts toward specified ends.

Here is a definition of leadership which at first sight seems to reverse the usual view of the matter by centering attention on those being led and on what they want and can be brought to want. Again, this is not the last word on the subject. But the emphasis on the led rather than on the leader is deliberate and is essential to a profound view of the whole relationship and its successful functioning. The reasons for this emphasis require further statement.

Objects in View Must Be Satisfying. Those being led must sooner or later find the object being worked for desirable and satisfying to them. Only so does the effort continue to grow out of self-propulsive and self-generating motives. Self-expression, a sense of registering in action, the feeling of zest in life's activity is a profound demand in each personal life. And it is satisfied in ways that are in one sense unique for each of us and in another sense common to all of us. The good leader is able to gather to his cause the self-expressive drives of his group because he knows how that self-expression comes to pass. It comes to pass, in a word, through the release and outlet of the creative parts of people's natures. *We are because we do.* And we do what we think yields for us a sense, however momentary, of power exercised and mastery assured. To lead well is to call to the aid of the leader's cause these yearnings for self-realization that normally impel the led and which only need imaginative direction into cooperative rather than purely individual channels, to enable successful group achievement to take place.

In short, the good leader is both spokesman or articulator of normal human demands upon life, and he is one able to see from his vantage point newer reaches of effort in which he and those led will discover unexperienced outlets of self-realization, self-growth, and associated power. Put in another way the good leader not only espouses purposes commendable to the led but with the led he helps to create new and better purposes through his knowledge of human nature, his unshaken faith in its creative attributes, his persistent reflective effort upon new ways and means to realize finer and fuller purposes.

Let no one think that this is mere rhetoric because it is stated in general terms. The department foreman who can bring a couple of score of individuals with their own special interests and desires into a sense of group purpose and effort to cut costs, improve quality, create a friendly atmosphere of cooperative effort, is a true leader of a much needed sort. He is enabling his group to experience the satisfying truth that in group efforts from which each personally benefits in status, approval, pecuniary reward, opportunity for advancement, etc., they are genuinely realizing themselves. The things they want of life can in a measure be secured in and through their common and associated exertions—that is, they can unless the leader's efforts and aims are exploitive and selfish and the benefits and results are not being shared with his following.

Corporate Purposes Must Be Sound. Then, when the foreman and his men have measurably succeeded in building an effective departmental group they still have together the task of integrating their group activity

with that of other departments till an entire corporate group sense is realized. This is a new and larger purpose growing out of success in realizing the primary one. And when that is seen to be the necessary next enlargement of aim, there arise considerations affecting alike the foremen, the rank and file, and the heads of the organization, as to the soundness of the objectives of the corporation as a whole to which loyalty is being summoned. Are they such as to inspire confidence among all the members, so that each worker in finding his own self-expression at work is also finding the corporate purpose realized? Or to put it in another way, must not the things the corporation sets itself to do be of such a character that in the striving for them each one in the entire group finds his own self at once protected and enlarged, and caught up into awareness of a larger self?

There are enough examples today of corporations pursuing different sorts of objectives to supply definite evidence as to where and how employees are brought into effective and harmonious working attitudes. And broadly speaking the companies which show this newer leadership successfully in action are those that have taken account of the basic desires of all of us—have made livelihood reasonably secure, have offset the fears of sickness, accident, old age, and death; have provided for training and promotion; have organized approval and incentives to better work and to creative suggestions; have been proud of the quality of their product and of the fact that it is economically distributed and reasonably priced. It is not without interest that a number of public service companies, where relations with consumers are in a measure controlled by legislative and regulative provisions, have found themselves in a peculiarly advantageous position from this point of view of being able to summon their employees to a worthy purpose. In such cases profiteering is presumably absent since the rate of profit is regulated; the service demands and responsibilities to the public are clear and direct; the appealing quality of the corporate purposes is limited only by the insight and progressive character of the corporate leaders themselves in interpreting them.

Under conditions like these the supporting situation under which good leadership can manifest itself is uniquely present. The whole psychological setting is of a character to predispose people to find part of their own self-realization in an intelligent pursuit of the corporate objectives. Good leadership has in such cases harmonized to a degree the personal aims and group aims—not by a process of compromise or subordination of personal desires but by a sounder, more liberating policy of assuring that each person as a person and the members together in a corporate sense live more fully in and through the progress of their associated labor.

Profits Alone Too Narrow an Objective. The loyalty of the led is, in short, conditioned upon the soundness and breadth of the objectives of the leaders. Corporations which are mindful only of profits to stockholders, which give no specific thought to employee well-being, can hardly expect to rally workers for long under a leadership that will thrill and grip. The companies where leadership works are those in which the ends sought are broader than money profits, and definitely envisage human satisfactions for the members of the corporate group in and through work. Get right with your purposes—

becomes an essential dictum for the good leader. And that means having purposes of such a character that there is a reasonable presumption that normal people will find some real part of their life realization in throwing in their lot eagerly and unreservedly with the corporate project.

Too often today the worker gives what he thinks he is paid for and nothing more. His working attitude is perfunctory, grudging, indifferent, or qualified in such a manner that no whole-hearted effort is forthcoming. Which is precisely what we should expect. It is really a tribute to human nature that in a purely wage relationship arrived at by rather arbitrary bargaining, people give as unstintingly of their effort as they do.

If this be thought a hard doctrine, one can only say that all the earlier experience along the old roads of employer-employee relations has led us nowhere. Essentially it has failed. Yet our machine civilization is relatively so young that the first dictate of wisdom is to realize that it is and should be in transition. As to what may be the forms and method of industrial government a half century hence, we do not have to be concerned. But it is of value to understand that the type of absentee-owned corporation trying to make unlimited dividends, or of closely owned family company, or even of bureaucratically run public institution or government department is *not* the type that promises to have survival value from this vital point of view of its ability to summon the best loyalty or to call into action the finest leadership. Our economic and political organizations have sooner or later to be set up in such fashion that they can expect through their leaders to call out the self-realizing efforts of the generality of mankind in what will be new and wholly unsuspected ways.¹

Good leadership, in a word, cannot in action be divorced from good purposes, from objectives which are psychologically as well as economically defensible. Good leadership commands loyalty not to a glamorous personality or to a hypnotic egotism. It gets its best expression only in a total corporate situation where human ends are in view and human satisfactions are by way of being realized.

The Leader's Personal Qualities

It is of value to speak briefly of those qualities of the executive himself that heighten his value as a leader. For such an analysis, however lacking in precision it can be at this stage of psychological knowledge, does at least show certain qualities which are capable of training. It is repeated often that leaders are born and not made. But this is not true. No doubt some are born better leaders than others. But everyone called upon to assume a position of executive leadership can by taking thought improve his own personal effectiveness.

Some of the important qualities which experience show to be requisite are: a bountiful endowment of physical and nervous energy, some technical knowledge of the function at hand, a better than average intelligence or

¹ See TEAD, ORDWAY, "Human Nature and Management," Chap. XIX. Also Tead and Metcalf, "Personnel Administration, Its Principles and Practice," Chap. XXXIV.

mental alertness, constructive imagination, knowledge of human nature, enthusiasm for the project in hand, some teaching ability with which goes a realistic time sense about the rate of change in people's habits and outlook, a sense of humor, self-confidence, and finally an underlying attitude of concern and friendly feeling for those being led.

Conscious Improvement Possible. From this list there are certain characteristics which by taking thought a person can alter. Up to a point physical and nervous energy can be augmented. Imagination can be aided by conscious attention to the process of reasoning and the conditions which minister to it. Knowledge of human nature can be improved by formal study and by experience. Enthusiasm can be developed if and when the purposes in hand become through conviction and feeling more and more fully one's very own. Teaching ability can be improved through conscious attention to methods of pedagogy as scientifically known today. Self-confidence can be improved in various ways depending on the particular source of the feeling of inferiority. A friendly and even deeply affectionate feeling for people can be developed.

This last is profoundly important—indeed it goes to the center of the problem since it peculiarly involves the individual's attitude toward life and to mankind as a whole. A good leader cannot be at heart a cynic, distrust people basically, or be fundamentally convinced that life's values are illusory. Of first importance is this faith he should have in the essential soundness of human nature and its capacity for development. For it is this he appeals to and builds upon. It cannot be too often emphasized that at his best the leader is not carrying on any subtle form of hypnosis. He is helping people to know themselves, to realize themselves, to work in a cooperative relationship, to find satisfaction in the whole project to which he as leader is committed and to which he seeks allegiance. To this end he must know himself, command himself, conduct his own inner life in wholesome ways, place value upon those elements which tend to make life better for himself and for others. All of which implies psychologically that his attitude toward people is friendly, kindly, tolerant, and confident of constructive and creative responses.

For this reason it is important to consider next some of the special problems of the leader in relation to his own inner life—problems of attitude, outlook, and mental habit, which help to make or mar the basic soundness of his human relationships. There should exist in his mental make-up no quirks which prevent his being sensitive to other peoples' natures, needs, aspirations, and struggles. Using the popular parlance of the day, he must not be too introverted—too preoccupied with his own personal adjustment to living.

The Leader's Personality¹

Effect of Inferiority Feelings. Feelings of inferiority in the leader are met with sufficient frequency among executives so that it becomes important to know what they mean and to what consequences they lead. For such

¹ For fuller development of this topic see Hart, Bernard, "The Psychology of Insanity"; V. V. Anderson, "Psychiatry in Industry"; Ordway Tead, "Human Nature and Management," Chap. IX.

feelings are almost sure to seek expression in ways that lessen his effectiveness. This is particularly true because so many executives today rise from the ranks and an inferiority sense is likely to develop. The self-made leader may come to a too serious feeling of his shortcomings due to a sense of inadequate education, of racial differences, of physical handicaps or of social distinctions which make him feel he does not "belong." And the tendency is strong in human nature where any such inferiority feeling becomes acute to compensate for it, to try to offset it by protective or defensive behavior of an exaggerated sort. The very short man for instance may shout, bully, and "talk big." The executive who is racially different from his associates or socially unacknowledged may either be too ingratiating or too insistent and arbitrary in personal dealings.

The possible sources of such feelings are numerous. One foreman may be compensating in his blustering attitude for having a wife who bosses him at home. Another may suffer the mental pangs of having been a youngest child at home and therefore having been "babied." And an only child may become a spoiled, vain, arbitrary executive. The son of a bullying father may display characteristics of too great timidity and submissiveness. These are only suggestions as to the kinds of personality problems to be met in dealing with people. And it is tremendously important that men who are to direct others should themselves be free of such mental disabilities so far as is humanly possible. Everyone who has the task of choosing and training leaders should be particularly concerned with the role that mental hygiene can play in helping to identify and to correct fixations and any bad mental habits and attitudes which individual executives may possess.

Freedom from inhibiting fears is an aspect of this problem which should be explicitly mentioned. Executive leaders need self-confidence and self-possession. If they are afraid of those above them or of those below them, they cannot do their best work. Respect and consideration for others are necessary attributes but they are entirely different from fears, both in emotional and in intellectual content. The leader who is afraid works under severe handicaps. His fears will sooner or later be found out and be worked upon to the detriment of all concerned. A poison is at work within him which eventually kills the other qualities essential to challenging the best in others.

The "Will to Power." What has been called the will to power is another tendency which may develop in an executive leader. By this is meant a love of exercising power for its own sake, a love of extending one's power unduly and for self-glorification. This is a subtle danger to which we are all exposed and it is something to watch for and check when evidences of it appear. The fruits of such an attitude are vanity, a desire to have one's own way in little things and to interfere in the carrying out of details, impatience with the mental limitations of others. The whole essence of true leadership qualities is so far removed from this craving for power over others that too much attention can scarcely be paid by supervisors of executive training to putting the emphasis upon *the educational role* of the leader as contrasted with the power role.

One manifestation of the will to power which is occasionally met is the disposition of a domineering executive to surround himself with men who do

not dare to or will not oppose him. The phrase, "*yes-man*," happily describes the type of individual who is likely to be found in organizations characterized by a one-man domination. The bad features of such a situation should be obvious. There is no frank critical consideration of problems on their merits; there is no development of the minds of the yes-men; there is a continuous further feeding of the vanity of the "chief"; and when for any reason he is removed the elements of sound organizations are all too likely to be found absent. The whole point of good leadership is to have the critical and creative experience of problem solving go forward continuously as a shared activity. Only in the pooling of ideas and in the building up of policies and methods by drawing on good ideas from all concerned, does the work of leadership show its best creative attribute. The will to power forgets all this and overrides the ideas of others without thought of assimilating and using them.

The good leader is, of course, not without personal power. His ability to influence is often greater than average. But the power comes through merit demonstrated, through general acknowledgment of abilities that command not only respect but affectionate devotion. The good leader *earns* his right to be powerful; and the power he manifests is not arbitrary and self-centered but grows out of his effort to build cooperatively. *He creates power by creating group consciousness and group morale.*

Leader's Idea of Himself. In a related connection mention should be made of the "personality image" which each of us carries of himself deep in his own inner consciousness and in relation to which one interprets and registers oneself in action. "What is my idea of what I really am?" is a question everyone should occasionally put to himself in the effort to be realistic, that is to say, to have one's mental image of oneself in close correspondence with what one really is. The executive with the "Napoleonic complex," for example, fancies himself like the great general and almost unconsciously tries to act like him with unfortunate results. The injunction to "know thyself" is not an easy one to obey but in relation to the executive's effectiveness in action it is a counsel of wisdom second only to which is the exhortation to "be thyself."

The Tendency to "Sadism." A further all but unconscious characteristic to be occasionally identified is what is called a sadistic tendency, by which is meant a desire to inflict pain on others as a source of satisfaction to oneself. This is a specially unfortunate trait for an executive to possess but it is one likely to show itself in the case of a man who has had a hard struggle to advance. "I've had to struggle for everything I have, so why try to make it easier for others. Let them go through the same fight I did." This sentiment is one widely held but it is unsound in essence. It is devoid of the educational outlook since it leaves the training and developing of others to chance. Hardship and struggle for self-mastery and progress are generally sufficiently present, and the man who is disposed to be a "hard master" is erring on the side of severity.

The more modern attitude is that everyone has to struggle with his own personal resources to make of them what he can and should. And the role of the executive leader is to facilitate the process of self-mastery and growth in

personal power by making the working setting of each of his group as much an educational setting as possible. It is one thing to "go through the mill" alone, unguided, determined and self-absorbed. It is another thing to find one's working associations made a conscious training process for the calling out of as much ability as a man actually has. Sometimes with this willingness to let others suffer for their own good goes a positive tendency to show power by inflicting pain. Some executives "pick on" people unnecessarily, or bully them, or keep them in a state of anxiety about losing their jobs. And all of these are expressions of a sadistic tendency which is thoroughly vicious.

The "Rationalizing" Tendency. The rationalizing tendency is another that should be consciously identified. We rationalize when we try to give acceptable reasons for acts which were done impulsively and for motives which we may be ashamed to admit to ourselves or others, or when we try to find plausible reasons for doing something we want to do but do not really believe in. A department head, for example, may find it easy to convince himself that one of his staff who is getting on in years is a poor worker, or insubordinate, or deficient in some respect. He makes this the reason for discharging him rather than have to face the problem of pensioning him a few years. The rationalizing process is so universal and it is often so hard to reason problems through to a truly sound conclusion, that a particularly insidious habit is here confronted. It has variations which are almost infinite in range. For example, among a group of executives one may differ from his associates on some matter of policy but he may convince himself that he agrees with them because he knows it will be safer for him to agree. The reason why it is important to consider this defense tendency is in order that the wise executive leader may be on his guard against rationalizing and may try to encourage honest and clear reasoning that will solve problems on their merits and disinterestedly.

"Grouches" and Irritability. Other more obvious forms of personality disturbance that constitute real handicaps to persons in leadership positions are moodiness, grouches, quick temper and irritableness. The origins of these may be difficult to trace in the individual case but they are not without definite causes which are to some extent removable. These conditions may derive from fatigue, from poor physical condition of stomach, liver, bowels, glandular activities, and the like. They may come from personal worries and anxieties preying upon the individual, from some unrealized "repressions" or "complexes." They are definitely a symptom of internal distress and should be viewed as such. They are frequently met but they are not normal. And every effort should be made by the individual himself and by others to help him, as we say, to "snap out of it." The therapy for these conditions cannot be gone into here but it is well known and available.

Leader Must Face Reality. The recurring note of this entire discussion of personality maladjustments is the importance of a realistic confronting of the facts about the sources and results of mental difficulties. An honest confrontation of reality is the first objective in all matters of personality adjustment and growth. The realities with which the leader is concerned relate first to the causes in his past experience of his own underlying attitudes

and mental predispositions, and second to the complex pattern of unadjusted human motives with which he has to deal in handling his staff.

On the first point, we are gradually coming to better knowledge of how to recognize failures to confront reality. In regard to less acute manifestations every one of us can be a mental hygienist for himself and for others. In its more acute phases it may be necessary to have recourse to the service of a trained psychiatrist. And it certainly has become one of the demands increasingly being made upon leaders and trainers of leaders that they know when mental quirks and abnormalities are present, sense how profound and dangerous to the person or the organization they may be, and be able to help individuals toward wholesome readjustment.

To be sure, the acknowledgment of the facts, candor, and insight in the presence of reality—this is only half the story. There must also come the deliberate process of what is usually spoken of as *reeducation*. The individual who stands confessed of mental maladjustments can be helped to see why he feels or acts as he does, why the maladjustment is unsatisfactory for him and for others, and how by conscious efforts he may establish new habit patterns in a new realistic relation to his whole environment. He can make fresh continuous contact with life which will give him a satisfactory adjustment. There is every reason to hope that a wider knowledge of mental hygiene and modern psychiatry among executive leaders both can and will come to pass and will bring with it a much happier internal personal life and much more amiable personal relations with others in business and elsewhere.

Leader Must Know His People. On the other point of the leader's realistic knowledge of what goes on in the minds of those he leads, it should be a matter of conscious intention and planning that every leader keep himself close to his people. He must have what William James so well called "the pungent sense of effective reality." Every device of office prestige, of pride of place, or inaccessibility, of lack of time to come close to people, which lessens this possibility is to be discouraged. It is possible and essential to know the temper of an organization and to know it intimately. And it is an end which can be achieved by a right personal attitude on the leader's part, without resort to informers or undercover methods of any sort. The good leader invites frank comment; he can be trusted by his people to sense difficulties and maladjustments, not in order to reprimand but in order to help others and to help himself to provide conditions in the organization and attitudes in its personnel which are more and more consistent with sound and harmonious operation.

This leads us, then, to a more detailed discussion of the relations of the leader to the led. The methods of his dealing with them must be studied. Better ways can be discovered and learned. The technique of the leadership relation has already been vastly improved in specific cases and it is now possible by training in example and practice to help every leader in this respect. The evidence of recent studies points conclusively to the fact that one of the most controlling factors in determining the happiness of the relations of the rank and file to the whole corporate project lies in the manner and tone of personal dealings between workers and their immediate supervisors. The

support which these studies give to the case for intensive work in leadership training has proved substantial.

THE LEADER'S RELATIONS TO THE LED

Leader Must Make Himself Understood. Perhaps of foremost importance in getting and keeping the relation of the leader to the led on a sound basis is his recognition of the necessity of clear communication and full understanding of the leader's purposes and wishes.¹ The leader must make himself understood. This implies clarity and simplicity of verbal expression. His vocabulary must be one that can be grasped; his enunciation must be clear; he must be sure that orders or ideas are correctly grasped. It is necessary to realize that words are the direct means for interchanging ideas; and words may mean different things to different people. From the point of view of employee reaction, the leader must not only speak in the employees' idiom but he must get at what his subordinates are trying to say, rather than pick them up on what they literally say.

Instructions should be explicit. If the leader is allowing those under him to work out the details of executing instructions, that also should be clearly understood. And other things being equal some latitude for personal judgment and choice in such execution is a good educational policy. Also instructions should usually be issued one at a time and not all at once.

Where the problem of communication relates to more general ideas and policies so that no question of giving personal orders is involved, the conveying of ideas is an even more difficult matter and deserves the most careful thought.

Assuring employee understanding of instructions has another aspect that relates to the time factor. A leader may himself devote much time to grasping the issues of a problem, and have thought it through or worked it through carefully for himself. Then when he comes to present it to his group the temptation is to be annoyed or impatient if they do not at once realize what he is driving at and agree with it. This is too much to expect. People do not come to understanding and to agreement with new proposals quickly. They too must go through the process of coming to understanding in much the same way and with much the same time allowance that the leader found necessary for himself.

Modern "Orders" Are Instructions. The new notion of the relation of leader to follower is not comprehended in the old idea that "orders are orders," that it is "theirs not to reason why." The new conception implies the maximum of understanding and mental grasp by all concerned as a basis of agreement and intelligent cooperation. It recognizes that action which is to be sustained, wisely directed and effectively carried through depends upon knowledge as much as upon enthusiasm. Sullen, dumb, submissive acquiescence is a bovine reaction at the pole farthest removed from the quality of the reaction the leader is seeking from his people. His effort depends upon a realization that the true springs of action are creative, self-sustaining and

¹ ANDREWS, L. C., "Manpower."

self-propelling in their essence. And they are of such a character only when people understand what they are doing.

Orders should always be given in a calm tone of voice. The tone of voice employed by the leader in all his contacts is of the utmost importance. He should try to pitch his voice low, avoid sounding querulous or peevish, and avoid using a sarcastic or ironic tone of voice. Sarcasm is a dangerous weapon in the leader's hands. And so is anger. The executive who has to resort to a show of temper to impress his men or to get things done is on the wrong track in his personal relations. Support and loyalty are to be won by fairness, firmness, clarity, a demonstration of competence, patience, and cheerfulness. These positive qualities secure the positive response.

Correction of faults or errors is an educational opportunity—not a chance for an emotional orgy on the leader's part. "Bawling out" has little place; and efforts at correction should usually be made privately, quietly, with the emphasis upon finding out how the difficulty can be prevented from happening again. Hence swearing at workers and using unduly strong language are an open admission that the real leadership relation is not present, that the attitude of the supervisor is wrong.

Favoritism in the handling of people is a fault to be severely avoided; nothing breeds greater disruption in the morale of a group, and the smaller the group the more obvious and fatal this can be. Merit alone should be seen to be the basis on which advancement comes.

Increasingly the importance of *good manners, courtesy, and cheerfulness of bearing* is being realized and insisted upon among executives. And the executive who appreciates the leadership aspects of his task will voluntarily fall into an attitude which implies these things. For the presence of these attributes shows both that the leader is in command of himself and that he has the necessary regard for the self-respect of those he deals with. They show that he realizes that they too are persons in their own right whose personalities are to be respected as of equal worth with his own.

Importance of Appreciation of Good Work. Another serious need in the leadership attitude is a willingness to show approval and offer commendation where it is merited. Appreciation of good work, if discreetly manifested, is one of the most important of the leader's assets. For there has been far too little of it in business although it is a positive and creative force of unexampled power. The yearning for approval from one's leaders and one's associates is assuredly one of the strongest traits in human nature; and every good leader is at pains to organize the expression of approval in definite and appealing ways. In fact techniques have been developed on this point which will repay more extensive study (see, for example, the writings of Robert B. Wolf and Whiting Williams).¹

In this connection it is important to be sure that credit is given where credit is due. Some executives tend to want all the credit and the praise, and seem afraid to allow any for their subordinates. They have been called "credit hogs." But it should be obvious from what has been said that the

¹ See bibliography at end of Chap. XIV, Tead and Metcalf, "Personnel Administration."

leader, who is niggardly of approval and selfish or dishonest in claiming credit for the good ideas of his group, is using basically unsound tactics. He quickly loses the confidence of his men and finds that new suggestions are no longer likely to be brought forward. Instead of inspiring his men he is inhibiting them.

Attitude of Friendliness. It was suggested above that the underlying attitude of the leader in relation to the led must be one of friendly regard. It is important to underscore this point. The friendly attitude is fundamentally the influencing attitude. Those whom we regard highly we try to be like. We are at ease in their presence; we understand their wishes and realize how they can be pleased. We become more sympathetic, more understanding, more discerning when we are friendly. The need for intelligence and discrimination is no less but to them is added an emotional quality which is like sun to the unfolding of flowers. This is not to be confused with an attitude of undue familiarity or of sloppy sentimentality. The essential friendliness that goes with the successful leadership relation implies rather a respect for personality, a realization that people have a right to preserve their personal integrity, that they become most fully effective working members of a group where the leader is sufficiently their friend to respect them as persons and call out the best that is in them. The good leader, in short, is a good friend to his following in the profound sense of rallying them to a genuine measure of their own best self-expression through participating in the activity of his group. He thus inspires confidence; he becomes more sensitive to personal maladjustments; he is able with them to meet emergencies better.

Finally, the right leader attitude implies a *good teaching sense*. Three aspects of this matter merit brief consideration. First, one should understand what the teaching process and the learning process are. Second, one should especially realize how to put people through learning experience. And third, the educational uses of conflict should be understood.

THE TRAINING EMPHASIS IN LEADERSHIP

The learning process requires that people come into effective command of some ability to do or be or appreciate something previously outside their experience.¹ It is the assimilation of a new skill, using the word skill in its broadest sense.

Learning by Doing. "Learning is learning to use." "The one who is doing the learning must do the learning." "No one ever told anyone anything." The truth that these statements are trying to convey is that only as the individual himself has gained motor and mental facility in a particular direction has learning truly taken place. The test of successful learning is ability to cope with the situation at hand. All the reading in the world does not make a good automobile driver, nor a good conference chairman, nor a good department leader. Reading can give hints and suggestions for use when one is in action. But one learns these skills by working at them. Skills are the result of an interplay of person (mind, muscle, etc.) and of surrounding

¹, ORDWAY, "Human Nature and Management," Chap. VI, .

environment or materials or situation. People do not learn in a vacuum. They learn because in dealing with persons, things or situations something necessarily happens inside themselves. And learning is always dependent upon these two factors, the outer and the inner, working together. The process can be forwarded by helping to control either aspect—the person or the environment. And much time and labor can be economized if proper attention is given to building up learning situations.

This is one of the tasks of the teacher or of the leader in his role as teacher. *He can help people to go through experiences out of which they are likely to acquire new learning.* Also he can inspire them to take the time and the effort necessary to learn. He can direct them to sources of suggestions and ideas that will throw light on the situations they confront. In a word he can help to shorten the learning process by directing it, by saving it from being wholly a clumsy groping of trial and error, by stimulating the use of reasoning as a substitute for and critic of motor experiments.

It is only possible here to suggest how much of educational psychology can be carried over for use by the executive leader. But the underlying emphasis can be given by saying that the leader as teacher is trying to guide and direct the experiences of his following in such ways that they will learn and grow as a result of them. People do not learn by being told or shown or preached at or lectured. They may sometimes secure a new idea or new inspiration in these ways. But until the ideas or inspirations have in some way vitalized the person's life and enabled him to cope with new situations in more competent ways, they have not been truly incorporated into that person's being—they have not been fully learned.

It is not necessary to dwell on this truth as it applies to the learning of the obviously motor skills. A machine operator of any kind is usually taught to run a machine in an approximately sound way. But when it comes to matters of attitude or of corporate policies or of skill in personal dealings and the like, leaders are apt to forget that people must do their own learning and that telling them of new policies does not mean that they have learned them, that telling a foreman to "handle his people in accordance with the company's personnel policies" does not at all assure that he will or can.

Learning takes time; it requires the active sharing of experience by the learner. Problems which he faces and realizes are the greatest stimulus to his wanting to learn. *Putting learners in situations which entail problem solving is one of the quickest ways to encourage learning; success in the process is measured only by the acquiring of proficiency.* Verbal glibness is not learning although it is often mistaken for it. Ability to verbalize or talk accurately about experience is itself a useful skill because upon it accurate communication depends. But in matters of business policy and practice talk has so often been a substitute for action and good intentions for good methods, that emphasis is necessary upon the fact that learning and knowing involve ability to objectify words into living experience.

A concrete example of the kind of situation found in industry where true learning is important is that of a department foreman charged with the job of enrolling his men for a contributory group insurance plan. Here the difference between learning about and learning, between information and

willingness to act, clearly emerges. And the tendency is for the important task of making the employees really understand and wish to participate in the insurance plan, to be slighted. The foreman may hold a department meeting, tell about the plan, and then act on the assumption that of course the men want it and try to sign them up on the spot. The fact that the proposal is of unquestioned benefit to the workers is no excuse for this summary kind of procedure. It is rather all the more reason for a painstaking method of instruction which will enable the workers and their families truly to appreciate what a good idea the insurance is and to realize the company is thinking about their welfare and trying to work with them to advance it.

This, then, is the second big item in the leader's grasp of training technique. He puts people through learning experiences. He poses problems which they must solve themselves in order to come to better terms with surrounding conditions. Take, for example, the not unusual situation of an organization head who wants to centralize hiring and other personnel activities but wants the foreman and department heads heartily with him in the effort. It is of comparatively little value merely to tell them what he wants and plans today. What he must do is to get them to want to try it. Suppose, therefore, he places more production responsibility upon them, expects more in output or quality or lowered cost. Then he says that to economize their time he is going to give them specialized staff help in recruiting new help and asks their cooperation in the experiment for a few months' trial. At the end of that time if the employing work is well handled the likelihood is good that the department chiefs will have come through a learning experience which will carry conviction and spell agreement to the new idea for the future.

The executive, who will apply this kind of teaching sense in letting people come to realize gradually that what he wants they too may advantageously want and work for, is the leader in the best sense. He has rallied his followers to a course of action through their own conviction and desire. He is working with the grain of human nature and not against it. He is harnessing knowledge, enthusiasm and creative interest in behalf of methods which he believes he can show to be beneficial. And to the degree that the followers have come to trust his judgment and believe in the honorableness of his motives, he will get quicker response, prompter learning, and faster progress toward the desired objectives. Put people or get people to put themselves into situations where the logical outcome of carrying through to a conclusion means that they learn some new method or come to have some new desire or appreciation—this is the formula that the creative leader must employ.

Educational Values of Conflict. And for this very reason the leader will find that conflict situations can be made to have positive educational value if handled in a similar way.¹ Take a case such as that of a company with an employee representation plan whose employees voted to ask the firm to sell them stock on some convenient basis. At first the heads of the firm were reluctant to consider the matter seriously. A certain conflict of interests

¹ See ELLIOTT, H. S., "The Process of Group Thinking"; A. D. Sheffield, "Joining in Public Discussion"; E. D. Smith, "Psychology for Executives," Chap. VI; Ordway Tead, "Human Nature and Management," Chap. XI, XIV.

appeared to have arisen. But this company was resolved to make such issues, when they arose, an educational opportunity for all concerned. It saw creative values in recognizing conflicting desires if the situation was handled under the guidance of wise executive leadership. The company heads were at pains to find out why this demand had arisen, what it meant in terms of employee desire, what comparable experience in other companies there was which might shed light on their own problem. Meetings were held with the workers; facts obtained; discussion back and forth went on for several months in the effort to find out how the basic ends the workers had in view could be squared with what the officials and stockholders also wanted. No effort at compromise was made. What was sought was a new arrangement or plan that would satisfy all. And eventually one was evolved. *An integration of desires* was achieved and in the process, all concerned learned much not only about the problems and hopes of all the rest but they learned to think out a new line of action that would represent a creative because newly created solution.

Under wise leadership, in short, the occasion of new conflicts of interest or desire can be made also the occasion of new efforts at associated thought, constructive planning, and cooperative action. Invention may take place which broadens the outlook, extends the experience, heightens the grasp of those participating. The process of conflict-solving can thus be a splendid educational venture. But it requires of the leader a realization of the opportunity presented, a patient teaching sense to make use of it, and enough insight to help guide the creation of a new formula or integration along the best possible lines.

Training the Leaders

In line with all that has been said about the nature of the learning process, the conclusion is inevitable that *the best way to learn to lead is to get practice in leading*. Workers who show executive and leadership capacities tend to emerge in the course of the day by day work, especially if higher executives are on the watch for them. Indeed that is one of the definite responsibilities that someone must have as organizations increase in size, namely, being on the lookout for workers who can become group bosses, for group bosses who can become assistant foremen for assistant foremen who deserve a trial as foremen.

At each level the problem is to enable the executive head to become as good a personal leader as possible, to stimulate him to try to qualify for advancement by further study of technology, personnel, managerial methods, etc., to give him chances to try out at executive work at the next higher level when someone is away. In the last analysis there is no substitute for trying out a man in an executive post to see if he shows leadership qualities. As to the length of such trials it is impossible to be specific here.

Next in value to the actual testing out of leaders in positions of executive leadership may be *the use of group conferences of executives* of a given level. To discover and encourage leadership qualities it is often well to rotate the chairmanship of these gatherings. They may, of course, be either production

conferences on methods and current problems, or they may be a series of conference meetings held for definitely educational reasons. In the former case the matters for discussion are usually ready at hand, growing out of current operating problems. In the latter case the personnel department usually takes the initiative in organizing a course of related topics. The topic of "man management," or some equivalent title, can usefully form the basis for a course in leadership methods.

The subject matter for discussion may be of several sorts. Actual difficulties with workers brought in by members of the group, problems they have had to meet in handling people are excellent material if well chosen. Or problem situations that have been disclosed to the personnel department either through grievances which have come to its attention or through systematic canvassing of employee reaction to management methods (such as the surveys made at the Hawthorne Works of the Western Electric Co. or the methods developed by J. D. Houser).¹ Or, again, the subject matter can be cases, problems or projects compiled by the conference director from more general sources but illustrating the principles at issue; and these should be made available in advance to each member for study for written analysis of the case by each conference member before the discussion starts.

Conference discussion of leadership problems cannot work miracles in making executives good leaders. But what it certainly has done in numerous instances and can do under wise direction, is to get executives to think of their work in new terms, to begin to change their attitude toward workers, to make them conscious of the importance of their personal bearing, conduct, manners, etc., in first-hand contacts with subordinates. It comes as a great surprise to many leaders to realize that the way in which they walk about their department overseeing the work may be a source of irritation to workers, that their tone of voice makes a difference, that constant criticism and no commendation is discouraging. Regarding a hundred details of this sort, the executive can and should be made to take more thought and pains and in the long run thus improve measurably the quality of his leadership.

Also in connection with case discussions, the use of *carefully selected books for reading and study by executives* has proved of great value. Suggestions of good books for this immediate purpose of encouraging executives to develop the leadership aspects of their work are given in the bibliography at the end of this section. Naturally it is important that such reading be carefully guided, discussed and digested. And this implies that the personnel executive or some equivalent executive must supervise such reading activity if it is to be most fruitful.

Again, successful work has been done by *personal efforts with individual leaders who do not seem to be making good*. One authority has reported that with foremen who seemed to be using their time ineffectually, he made them write a report of their progress and that of their department in the last six months. This report was the basis of personal conferences; and then the foremen were asked to write another statement of their plans for depart-

¹ HOUSER, J. D., "What the Employer Thinks," Harvard University Press, 1927.

mental development in the next six months. This too was used in private discussion between each foreman and the personnel manager; and the result was that these executives came to think of their work in new and more productive terms. Similar personal efforts can be made with individual executives of any rank; and by conference, directed reading and friendly personal analysis great improvements can be obtained by a strong personnel manager who has the confidence and respect of others in the executive staff.

In short, there is at hand a considerable and growing body of experience as to ways and means of making executives leadership conscious and of cultivating leadership qualities in potential personal leaders. The chief requirement today is the desire of organizations to have some one, capable, top-line executive who is charged with this developmental responsibility. Where the need has been recognized and one or another of those methods employed the results have been definite, obvious and gratifying.

Conclusion

There are two or three points out of this whole discussion that merit summary emphasis. In the first place, the leadership situation has been shown to have certain aspects which are functional, impersonal, inhering in the position and where the need for leadership grows out of the relationship; and it has certain aspects which are personal, related closely to the calibre and characteristics of the individual who holds the executive post. It is important to make this point because it suggests the need of an attitude on the part of leaders which is not conceited or self-enhancing. In a real sense the leader is the servant and counsellor of the led by virtue of the position he occupies. And it points also to the importance of paying attention to those personal attributes of bearing, manner, attitude, physical conditions, etc., which make or mar the executive's success as a personal leader.

Secondly, good leadership is conditioned by sound, broad, unselfish purposes, objectives or aims on the part of the leader. He cannot expect to get people to want to be led to do things which are against their own interests, which contribute only to the good or gain of others. Fortunately personal enhancement, self-realization, and growth do not come for most of us in isolated, unrelated efforts of our own. The social world and the world of economic effort are areas of associated activity and people gain certain deep satisfactions through cooperative group efforts of a constructive character. It is not foreign to our natures to want to work productively in association with others. The right quality of leadership, in short, does not involve a strain on the loyalty of the led. But the supporting conditions for corporate efforts must be right for the individual if he is to be expected to lend genuine support and aid. Here is where the role of the leader is distinctive. He must be able to show in action, experience and results that the good of the led is tied up in concrete ways with the good of the corporate whole. And this he can only do if the corporate aims are liberal, plural, and inclusive.

In the third place, the leader's method of demonstrating the safety and social soundness of the corporate aims from the point of view of the led

must largely be by means of the actual experiences through which the employees themselves go. If in the course of such experience they find that they get satisfactions for themselves while also forwarding the leader's aims, the leader has succeeded in really bringing about a change of purposes. People learn of the validity of purposes through situations where they have experienced the benefits of those purposes. Moralizing, lofty sentiments, generous managerial principles or intentions—these are of less than no account until translated into working policies and specific methods which the workers discover in their relations with the company. Workers will learn to follow the leader where they find in action that the leader's desires and their desires are in comparative harmony. All of this is but another way of saying that the generality of people's desires are not anarchistic or selfish or exclusive. The new leadership is based on the assumption of the soundness of human nature, on a realization of its capacity for creative effort, growth and cooperative achievement. Where we have so often fallen down is in not providing supporting institutional conditions and policies, that are calculated to draw out the best in human nature.

Fourthly, leadership qualities are not a mystery or the secret of a few born geniuses. One of the first things to be learned in business is that we have to work with the human material that we have. Of course, an executive staff of low calibre can gradually be improved by substitution and replacement. But beyond that point the task of management is to make the best possible use of the human resources at hand. And with careful intensive training and personal cultivation, experience shows that leadership ability can be vastly improved. And the way to train is to have the desire, and to start to train along lines that are fairly well established.

There is an old saying that "the gods sell all things." By which is meant that what we want hard enough to work for can be obtained. And this is eminently true of the task of transforming our tens of thousands of executives into inspiring leaders of men. The conditions and requirements imposed were never so clear as now. The disposition of corporate groups to count the cost of getting good leadership was never so favorable. Even on the side of the broadening of corporate purposes to include the aim of helping to fulfill ends of personal realization among all its members, we are witnessing a slow but inevitable shift of perspective. The corporate form as such is relatively new and we are undoubtedly but at the beginning of efforts to build corporate structures in such ways that the rank and file can find happiness and satisfaction in productive economic service through loyal corporate effort. All this implies wise, far-sighted, imaginative leadership up and down the line. But it is for this leadership that we wait and to this leadership that we look to make economic life tolerable and truly contributory to the enhancement of living for all.

CHAPTER VII

TECHNIQUE OF GROUP ACTION

COMMITTEE PROCESS AND COMMITTEE CHAIRMANSHIP

BY JOHN J. HADER

Present Need for Committees in Industry. The subject of committees in industry and their relation to general administrative functions is one that is receiving an increasing amount of attention by students of management. The impact of specialization combined with the influence of large scale production has forced upon those who are concerned with administrative problems the necessity of discovering ways and means by which the disintegrating influences of these two major forces may not only be countered but also utilized constructively. From time immemorial men have come together to "talk things over" but it is only in recent years that this getting together to talk things over has itself been made into a specialized function in industry.

Need for Definition. This is an administrative problem about which there has been much undefined thinking. The war and its attendant situations threw upon us a host of organizations and organized effort attempting to deal collectively with common problems. From the League of Nations down to the details of local community we have given ourselves over to dealing through committees with what had before either been taken care of by individuals or as in many cases had been left entirely undone. In industry elaborate schemes of employee representation and allied forms of joint dealing have been set up while in the higher reaches of management, committees of industrialists representing such industries as oil have been holding regular sessions. Some manufacturing firms have put their management on a committee basis to seek through consultation with those concerned the best solution of the problems at hand.

The term committee as used in common speech is usually taken to mean some representative body elected from a larger body or selected by an individual. It implies a togetherness for purposes of considering matters of interest. However broad or narrow the subject matter for consideration may be; however limited or unlimited the authority; however conclusive or inconclusive its consideration—the general term committee is used as a label and therein lies the reason for a good deal of the difficulty that creeps into the current thinking about committees. It might be lessened if we were careful always to give special names to special kinds of committees.

Purposes and Kinds of Committees. Before entering into a general discussion on chairmanship and its relation to committee process, a word must

be said about the purposes of committees. Probably no two people would agree upon anything that was set up as a final classification of the functions of committees. Committees are means to ends and these ends in view are as varied as all human purposes are varied. According as they are fitted into specific aims do they receive their specific character.

The three most general kinds of committees in industry are management committees concerned usually with matters of policy and administration; joint committees of management and the rank and file employees and finally employee committees in which the management does not share or if so only upon request. It is with the first two kinds that this discussion will deal. Oliver Sheldon, in his book "The Philosophy of Management" says:

Committees can only be of four kinds; firstly, executive in the sense of making decisions upon matters brought before it. Secondly, a committee may be co-ordinative in that it brings together certain individuals, representing certain definite functions or parts of functions for the purpose of ensuring that the work of each function is conducted upon lines corresponding to and harmonizing with the work of other functions. Thirdly, a committee may be advisory in that it brings together certain selected individuals to whom an official who requires special guidance in a difficult situation may refer. Fourthly, a committee may be educative in that it forms a means whereby an official may keep his staff regularly notified of events and policies.

We are not concerned with any question about the functional validity of any given set up of administrative or employee representation committee. Our considerations are of another sort. Granted that the committees are in operation, how are they being run? If the above or any similar classification of the kinds of committees is accepted, it will be seen at once that the processes of the committees will of necessity vary with the purposes. Arranging the above four kinds in a scale like this: executive-coordinative-advisory-educational, it will be seen that the purpose of the first, the executive, is to *do*, that is, to decide something. The coordinative committee is essentially *adjustive*, it does not decide but it may create a new situation. The advisory committee *gives* something, that is, its purpose is to deliver, it is meant to draw something out of the group. Lastly, the educational committee *gets* something, namely information is passed on to the membership. It will be seen that there is in this scale an arrangement according to formality, according as the matter is one calling for precision and definiteness in the way the committee is handled.

Chairmanship Functions. Executive committees, such as boards of directors, would of necessity have rules and regulations for the conduct of business. The problem of chairmanship in such a committee is essentially one of knowing how to steer the procedure down the well-defined channel provided by the constitution and Roberts Rules of Order.

On the other extreme of the scale is the educational committee. The receiving of information is no complicated process and the chairman's function when he is not announcing speakers or reading pronouncements is essentially that of a discussion leader.

It must not be assumed, however, that any given committee consistently adheres to these precise purposes at all times. At any one session it may

assume all four of the functions mentioned above, usually without either the chairman or the committee being aware of the change. And with the formal change may also come a complete change of mood in the group of which the chairman needs continually to be aware.

It is, however, in the two middle areas that the most delicate problems in chairmanship are called for. The functions of the coordinative and advisory committees cannot be as sharply defined nor are the functions of the chairman as easily to be determined. It is here that vaguely descriptive terms are used when people try to give the attributes of a successful chairman. They will say "he is a born leader; he has personality; he gets along with men."

Enlisting Participation. The success of an advisory or coordinative committee depends above all upon the free flow of ideas that is started; there must be an interchange of experience, for unless the chairman can enlist participation the committee is apt to have little success. Secondly, because of their informal nature, and the fact that there is usually a minimum of prescribed rule, the committees of this sort are dependent upon the chairman's conception of what the committee process shall be. What is easily overlooked in the setting up of committees of this sort, however, is the job relationship between the chairman and the members of the committee, and the way this may affect committee process. In a committee known to the writer the chairman stated his opinion of what he thought should be done, following the discussion of a certain case, and in concluding remarked: "How do you feel about it, am I wrong?" This chairman's conception of the way to get discussion in the group appeared to be that it was first his duty to state his opinion. In this case, for one of the members to answer that question directly and affirmatively meant that he would go counter to his superior for each member of the group was responsible to him.

Impersonalizing the Issue. In this case the "You"—"I" relationship created by the nature of the chairman's question "How do *you* feel about it, am I *wrong*?" brought in response a series of personalized replies that left the situation confused and instead of factual statements, which would have presented a clarified situation from which a decision to act might have been automatic, opinions were evoked and the chairman in confusion resorted to ridicule of one of the proposals and then in defeat deliberately changed the subject without reaching a conclusion and without consulting the group as to his reasons for so doing.

The question of impersonalizing the issue in committees is one that is not always recognized by chairmen and especially those chairmen who are directly responsible for the work of the group involved. Their position of power, the consideration given by their realization that the group in question is advisory to and functionally subordinate to them, places them in a position where only the most skilled and objectively minded can detach themselves from their authority and see the question merely as one of the group.

Can the opinion be separated from the person giving it? Every time we state our opinion there stands behind that opinion, as a soldier on guard, the self, the ego, the "I" of the speaker. This I wishes always to be unchallenged, it wants to reign supreme. Every one of us has the germs of

this autonomous I within us. We all tend to identify *ourselves* with our *opinions*. Now when that opinion giving I happens to be the chairman, who represents not only the chair as a group leader but as power factor and determinant in the life of every member present, a wholly different situation is developed.

Bringing Out Differences. If committees are to be genuinely advisory, it is well to ask how is advice obtained? When a man sets out to seek advice on a question we may assume that he wants not so much that people should agree with him in his position, but that if they differ with him they should express that difference and then tell why. Where, however, the chairman is not only the leader of a group but also the symbol of authority, it can quickly be seen that a different situation will prevail. If we assume that a primary reason for having committees is to bring out differences of opinion or to reflect different viewpoints for the purpose of obtaining in that way a more creative conclusion, then the question of how we are going to bring out these differences is fundamental.

Should Department Head Be Chairman by Virtue of His Position? The function of the technician is non-partisan. Can the chairman as technician see it as his function so to instrument his members that each and every one justifies the time he spends in the group by a proper rendering of his contribution? Knowing as much as we do about individual and abnormal psychology, we have long since learned that this cannot be left to chance. This raises the question of the functional validity of having the department head serve as committee chairman merely by virtue of his office, since what is wanted as a result of the group process is not that someone should have "his" way and get the group to agree, but that the situation in each problem should be uncovered to the fullest extent possible, and thereby reveal what form of action should proceed. Is this not a problem of pure method? The department head, as chairman, has an interest (a desire) in the way the group should proceed. His conduct of the meeting will thereby be determined by that interest. But it is also possible that his absorption in the details of the business at hand may lead to an overlooking of important aspects of his function as committee chairman. If the situation and not the personality is to control, is it not possible that some way can be found by which the fullest participation of the group is insured to yield a maximum of return? Can a way be devised that the chairman, whatever his rank, sees it as one of his first duties to uncover the "total situation"? *

Kinds of Conclusions. We need then to see this problem of technical chairmanship in the light of two questions: First, what kind of results or conclusions are desired and second, by what steps can they be reached? A guide to thinking about the results of committee process is the following chart with its scale of conclusions arranged according to the kind of participation involved (see Fig. 1, page 1680).

To the left, at the height of the line of individual dominance is **ACQUIESCENCE**. This is equivalent to someone ordering the group. The next less pronounced stage of dominance is **ASSENT**, that is, someone tells the group but does so with an element of explanation. In **COMPROMISE** we have the typical debate pattern where the group is divided. In a **CONSENT** agreement the

group has been carried along by developing the ideas to a point of willing acceptance, while in an *INTEGRATION* it has been possible to utilize fully the differences in the ideas of the group and embody them into a conclusion so that each feels that he gets essentially what he wants.

Space will not permit going into detail as to what is embodied in each of these conclusions so far as the *esprit de corps* of the committee members is concerned. We all know the wholesome effects that come from participation in a fruitful group process. We also know equally well that humiliating feeling that comes when we are "told where to get off." If the chairman can keep in mind something of what is involved in the conclusion that his group reaches he has gone a long way toward getting valuable group process.

Sectionalizing the Conference Procedure. The second problem of the technical chairman involves his ability to sectionalize the meeting and see it on its way toward the conclusion. He must see something of the parts of the picture which finally make up the whole, and he must see it as it proceeds.

Fig. 1.

There have been attempts made of late to depict the exact stages that should take place in a committee on its way to a conclusion, but our researches to date have shown this to be improbable. There are frequently a variety of ways of reaching the same goal, depending upon the purpose in view. It can only be said at this time that there are various possible goals and varied methods of reaching these goals.

It must not be overlooked, however, that frequently the most important factor for the success of a committee's deliberation is outside the committee meeting. Are the issues kept open so that the group actually can work toward a joint conclusion, or is the matter all decided in advance by one or both parties?

As an illustration of what may happen in such a case this record of the functions of the chairman of a joint committee is shown. It will depict some of the sections into which such a procedure can be broken down for analysis (see Fig. 2).¹

¹ The chart on discussion from which this analysis of chairmanship is derived is part of a study on methods of analysis of the joint committee by John J. Hader and E. C. Lindeman, "Social Hypothesis," Harcourt, Brace and Company, 1931.

FIG. 2.

A Joint Committee. Sequence of the discussion from the point of view of the chairman's activities, as shown in Table I:

In this case the chairman was acting in a triple capacity:

1. He was presiding officer of the group.
2. He was a representative of management.
3. He was an expert in the sense that he probably had more knowledge about the problem presented than any one else there.

A fourth factor might be added, namely, that he was the highest ranking representative of the company at the meeting and therefore in a very direct

sense responsible for the work of those in the committee. A list of the functions he was performing during the procedure of the committee follows:

CHAIRMAN FUNCTIONS

1. Factoring out the problem.
2. Refining the problem.
3. Specifying the problem.
4. Localizing the problem.
5. Rebutting argument.
6. Justifying management.
7. Putting it up to the group.
8. Testing his position.
9. Supporting his case.
10. Adding new facts.
11. Making comparisons.
12. Introducing related problems.
13. Stating the problems in inclusive terms.
14. Summarizing.
15. Closing the discussion.
16. Reopening the discussion.
17. Concluding the discussion.
18. Asking for a recognition of principle.
19. Asking for confidence.

Since in this case it was the purpose of the chairman to get the group to agree with him, or to put it in another way, since he did not wish to have the group bring him to a position of admitting a desire for change, it may be asked, was the method he used the most advisable one for his purpose? Note that from numbers one to four he was engaged in an analysis of the problem. As early as number five and six he was rebutting and justifying. He did not put the matter before the group until number seven and then it was necessary for him to debate the matter as indicated from nine to thirteen.

He then wished to conclude and attempted to do so but was obliged to reopen the discussion upon continued pressure from the group. The final conclusion was in the nature of an assent lacking the positive values that might possibly have been obtained had he used a method that would have involved some such procedure as this:

1. He might have invited the group in to analyze the problem with him.
2. He might have had them reveal their ideas on the subject by questioning them.
3. He might have held his own opinion in abeyance.
4. He could have taken a positive, explorative instead of a negative defensive position.
5. He might have thus obtained an understanding of the conclusion by all through their participation in it.
6. Thus, there would have been something in that conclusion which all could carry back into action.

Little has been said of the participation of the members of the committee. We have spoken of the difficulties that opinion giving can create and of the

inhibitions to participation that may come unless guarded against, when the chairman is also a power element in the group.

It is important to study closely the group's responses to facts, questions, and opinions. We need to observe the vitalizing effects of personal experiences, their place in the meeting and of the tone-giving qualities of humor we are all aware.

THE AUTHORITIES, FUNCTIONS, AND LIMITATIONS OF COMMITTEES

By E. C. LINDEMAN, *The Inquiry*

When Mr. Mussolini became Dictator of Italy, he discovered very soon that there were 150 holidays in the country, and that, if all the working people took advantage of them, they would be on holidays at least half the year. As soon as Mr. Mussolini discovered that, he issued an ultimatum which cut down the holidays from 150 to 40. If we had Mr. Mussolini in this country, one of the first things he would discover would be that we spend an untold volume of time and energy in committee meetings, and I should not be at all surprised, were he here, if he would issue an ultimatum cutting down the number of committee meetings one would be allowed to attend.

After all, the committee is an Anglo-Saxon product. It grew up with other Anglo-Saxon forms. It was one of the earliest, if not the earliest, representative social form. It became thoroughly incorporated not only in our legal and governmental systems but in our voluntary social system very early in the history of the English-speaking people.

We have now in Congress, in our voluntary groups, and in our jury system, a thorough-going series of committees which actually do, I presume, control our lives. If we knew where most of the authority in American life was generated, I presume we should discover it was in committees of one sort or another.

It is from that point of view that they do become vitally interesting; interesting not merely as devices but also as experiments, as something which can be reduced to not merely a waste of time but to actually creative enterprises.

Committee Difficulties. 1. *Irrelevant discussion* is one of the first difficulties with committees. Time is wasted, and people lose composure because discussion does not stick to the point. What contributes to irrelevancy? Why are people irrelevant? That is really a psychological question. If we knew why people were very good technologists, or good executives, good foremen, good workers, yet not good thinkers, or why when they get into a group they fail to think consecutively, we would be on the trail of one of the therapeutics for good committee function.

2. A *self-centered chairman* comes in with an idea he wants to put over. A chairman may be more interested in his own ideas than in the ideas the committee might have. It is possible that he is not only self-centered, but also probably too authoritative and insensitive to what is going on in the

other fellow's mind. This kind of chairman does not think what somebody else may have to say important enough to try to get it out and see its worth.

3. *One or two members of a committee may desire to impress a superior.* This may be done by irrelevant discussion, over-emphasis, or they may agree too readily with the superior. They may agree with the chairman. This is the kind of person who, without regard to facts, wants to impress people with all he knows, not only on the particular subject under discussion, but on things that have nothing to do with the discussion. Sometimes this kind of person impedes the whole process, not only by agreeing with the chairman, but by using another kind of superficiality—by disagreeing.

4. *Failure to state the problem or the issue before the committee at the outset.*

5. *Failure to set proper limits on the scope of the committee's interest or activities.* When a committee is appointed, whoever appoints the committee should state definitely what the committee is to be interested in and the scope of its activities. Failure to do that leads to useless discussion of subjects in which the committee probably has no interest. This leads to loss of time and energy because it is not the kind of problem for the committee to deal with. It involves such conflicts as frequently arise when the policy-forming and policy-executing functions of the committee are not sharply distinguished.

6. *Failure to come prepared for the topic.*

7. *Indifference of some of the members of the committee.* They probably disbelieve in the manner in which the committee is functioning. Consequently they assume an indifferent attitude and are a hindrance rather than a help to the committee process.

8. *Some members of committees do not get a chance to talk.* This may be because the chairman does not welcome their participation, or because he shuts off the discussion; or because two or three other members have dominated the committee so that everyone else feels unwelcome.

9. *Chairmen do not always properly phrase thought-provoking questions* with which to stimulate the group into active participation. This is also a problem for the committee members. Many of them think they are asking questions in committees when they are really making statements. Some chairmen also cannot distinguish between thought-provoking and crystallizing types of questions. The first questions should be of the former type, then at the proper time the chairman should be able to sense when the information has been brought out, and by a proper series of questions crystallize the discussion. In this way the group will have done the thinking.

10. *The chairman fails to postpone a statement of his own position* in regard to the subject under discussion. He already has a solution to the problem, and he voices it so early that the others withdraw from the discussion, assuming that since he has made up his mind, the matter has been settled.

11. *Politics or ulterior motives* very frequently affect committee process adversely.

12. *Committee members are frequently not qualified* to discuss the subject. They may lack either knowledge, or experience, or both.

13. *Committee process may be hampered because some people hold fixed ideas.* These fixed ideas prevent their paying any attention to what is going

on in the discussion, and they wait only for an opportunity to voice these ideas in an unchanged form. Others have fixed attitudes toward the chairman, or somebody in the committee, and this emotional set stands in the way of free discussion.

14. There is a tendency of the various members of the committee, including the chairman, to *jump to conclusions* before facts are presented. Sometimes they do not have sufficient facts, in other cases they may fail to make use of them.

Purposes of Committees. Committees may be used for:

1. Informing, educating, selling company policy.
2. Making policy, executive guidance.
3. Changing attitudes, coordination.
4. Producing goodwill, absorbing conflict.

Committees at times assume executive functions. The difficulties with entrusting executive functions to a committee are:

1. An individual is always on the job, a committee has to be called together.
2. People in groups will often do things in a way that they never would do as individuals.
3. They accept responsibility in a much lighter fashion.
4. In a case of mistaken judgment the responsibility can be focused upon an individual but there is a dilution of this responsibility when it is laid at the door of a committee.

Because insufficient attention is paid to the selection of the personnel of a committee they frequently are dominated by a few members. They may be totally ineffective due to incompetence or the members may simply lack the knowledge for dealing with the subject. A committee should never be set up unless there is a definite function for it to perform which cannot be performed in another way, and then its duties and authorities should be explicitly stated.

Getting Results. Assuming that there has been an adequate definition of just what the committee is to do and assuming that the committee personnel was wisely selected both for capability and for compatibility, the chairman is the key to the committee's success. He is like the hostess of a dinner party; he must know how to keep up the tone of the meeting; know the likes and dislikes of each member, draw this and that one out and at the same time be able to control the more talkative ones. The job requires diplomacy and a knowledge of human nature; a czar would never do.

From the mechanical side of committee operation as distinguished from the human side the necessity for adequate preparation in advance is important. Hours of time must be spent in getting up the docket, in framing the questions as well as putting them into an ordered sequence. If a committee is to make deliberations on an important matter the members should be given advance information before the committee meeting. This will save time and nerves in the committee. At the same time that this advance preparation should be thorough—it should not be too obvious, nor too cumbersome so that it gets in the way of the committee's progress nor rob it of the spontaneity that is so necessary to vital committee process.

The chairman too, should know how to go on from step to step in an ordered sequence leading up to the conclusion.

In addition to the suggestions made above, questions such as the following are involved in the technique of committees:

1. Is lack of preparation more common than lack of skill on the part of the chairman?
2. Is a different kind of skill needed for groups of varying size?
3. Is there a progressive ratio in the increased size of a group with:
 - a. The difficulties of successful committee process?
 - b. Skills required in achieving desired results?
4. Do we need a set of psychological rules to supplement Roberts Rules of Order, which merely establish logical sequence?
5. It is generally assumed that individuals are stimulated by the presence of the group. Is it likely that the reverse may also be true, namely, that people are bored and fatigued and driven to lethargy by the group under inadequate leadership?

The Problem of Authority. Where do groups get authority? What is the relation of authority to function? Can a representative body have authority without responsibility?

If we had had an opportunity to explore the background of these questions we should find our answers in the areas of contact on all the levels of authority there are in American life, and we should have to begin with the public itself. Some of the authority vested in business comes from the public and some also comes from the government: some comes from the stockholders, and some from the directors. And then, within management there is a continuation of this sequence of levels of authority beginning with the executive officers, passing through the technologists to the supervisory force, and finally to the workers. In this whole series there is a gradation from the extensive-general to the intensive-particular authority over the problems of industry.

We have been reminded of late by Miss Follett that authority goes with function.¹ If this is true then we must ask in the case of each committee that we are concerned with: *At what level in this above mentioned hierarchy of authority does it function?*—If it is a committee of directors, quite naturally its functions will be different from those of a committee of management on the supervisory level. If it is a committee of workers organized in a system of representation, their functions will have been described in their constitution. Their authority will be derived from their function and there need be no thought of a clash with any other level.

It must not be overlooked that responsibility and interest are very closely related. How often are subjects that are only remotely related, not only to the interests, but to the functions of committees presented to them?—And in the modern factory what added factors are there outside of a man's job to give him an interest in the operations of the company as a whole? Probably most of the members of the management group would not deny the axiom that every committee member has an active interest in committee

¹ FOLLETT, MARY P., "The Illusion of Final Authority," *Bulletin of the Taylor Society*, December, 1926.

affairs that concern his job. It is to be expected, too, that as a committee member he will thereby take responsibility for these items. But is it not true that almost any subject presented by management to a committee would in the end be somebody's job? Then how does carryover, or transfer of interest come about? How do we take a share of responsibility for other people's affairs unless these are also in some way our affairs? It is possible that those companies who have a wide distribution of ownership among the management and employees would be able to contribute some very vital suggestions for solutions of the problems concerned with authority, responsibility and interest. In other words there must be stimulation of interest in the areas beyond the person's immediate job; otherwise, a committee will cease to be a representative body functioning on behalf of a whole, and will degenerate into an arbitrary set of individuals bickering over problems of self interest.

CHAPTER VIII

PUBLIC RELATIONS

CORPORATION CONTRIBUTIONS TO COMMUNITY WELFARE AGENCIES

BY MARK M. JONES, *Consulting Economist*

It is important to analyze some of the problems which emerge from the fact that corporations doing business in several or many local communities are called upon to make financial contributions chiefly for local social welfare projects, and, in most cases actually do expend large amounts in response to such requests.

Subscriptions to, and memberships in, trade, professional, or other business organizations are not discussed; these present problems that are very different anyway, and should therefore have separate treatment. Nor are contributions not directly financial in nature included.

One other preliminary statement seems important: it is, that while many of the larger corporations expend several hundreds of thousands of dollars annually in the form of contributions, the problem lies in a field in which practice is still very much ahead of policy.

The Problem. The immediate problem is that of working out a rational apportionment, between the primary elements of a community, of the financeable cost of necessary local social welfare work. At the same time it is of highest importance that this be so done as to place no obstacles in the way of careful study of social welfare problems and periodic reorganizations in the hope that work of this kind may ultimately be reduced to a minimum. As understanding of the situation advances it may become apparent that there are other and better ways to deal with the problems presented.

The term "rational apportionment" is used in defining the problem because it seems evident that most social welfare work has relied mainly upon emotional appeals to attract support, that emotional appeals have little continuing power, and that now, after an existence of many years, we should begin to see reasons why such work is necessary and desirable. The term "primary elements of the community" is used because it is of course obvious that the nearer to the source of production wealth is tapped, the smaller should be the outlay to secure it for this purpose. "Financeable cost" is mentioned particularly because local social welfare organizations as a rule are and should be making steady progress in developing earning power with the result that a steadily decreasing proportion of the total expenditures of most of them must be financed by contributions. "Necessary local social welfare

work" has been mentioned because it is the view of most persons who look into the situation critically that there are grounds for doubt as to whether all of the expenditures that are being financed under this title are really necessary.

In considering the nature of the problem further, it seems desirable that we first remind ourselves that the corporations comprehended by the title of this paper are those which are in business, that business may be described as exchange of values, and that value may inhere both in goods and services. Our economic system contemplates that business shall employ capital and that capital is wealth used in or available for production. The Duke of Argyll observed that "wealth is (1) the possession (2) in comparative abundance (3) of things, (4) which are objects of human desire (5) not obtainable without some sacrifice or some exertion, (6) and which are accessible to man able as well as anxious to acquire them." John Stuart Mill pointed out that "what capital does for production is to afford the shelter, protection, tools and materials which the work requires and to feed and otherwise maintain the workers during the process."

Root of the Problem. It seems to me that the words "ability" and "maintain" in the preceding definition and statement on wealth are at the root of the problem. Corporation contributions often may be said to aim to maintain and develop the ability of men so that they may make the sacrifice or exertion of value in relation to the purpose of the corporation which will enable the men to acquire objects of human desire. The present world economic system is based on the ability of men, although of course I am not suggesting that it is based on this alone. So it seems that the ability of men and women must be maintained and developed if we are to have an economic system at all, and it is from this base that one's course must necessarily be charted in considering this subject.

Minimum Standards of Community Service. It also seems necessary at the outset to consider that custom has established as necessary, in many communities, various services to maintain and develop the abilities of men, which when first proposed or initiated were only deemed of value and importance by a very few persons. As we look out upon the situation now, however, it seems that most of these social welfare services have been created to round out local communities in order that there may be present within them the minimum standards of community service which the majority of residents think necessary. Social welfare agencies usually maintain most of the services not otherwise provided, yet necessary to induce persons to live and express their abilities by working in the community in question rather than somewhere else. There is a competitive aspect as between communities that should therefore be held in mind. It is also well to stress the fact that we live in an economic era and, under the conditions which grow out of this fact, social welfare work, like religion and education, only has meaning and vitality in relation to its economic sub-structure. Let us therefore consider local social welfare problems more specifically in this connection.

1. *Health* is necessary, to maintain ability, and before ability can be well or continuously expressed. Various agencies exist in increasing numbers to establish and safeguard good health, not only by effecting the cure of disease but by aiming at prevention. Thus we have a group of local social

welfare agencies which includes hospitals, dispensaries, nursing services and health promotional agencies of various kinds.

2. For many reasons, there are *individuals and families that at the moment are not on a sound economic basis* because they have no tangible wealth and are without ability that has an exchange value. This condition may result from voluntary or involuntary causes, but may be none the less real and the individual or group must be given relief by relatives, by friends, by private organizations existing for the purpose, or by tax-supported agencies existing for the purpose. The local social welfare organizations coming within the scope of this discussion at this point are usually privately financed and give financial assistance and advisory service, maintain homes for the aged, and operate protective and correctional agencies for adults.

3. Then there is the fact that approximately 30 per cent of our population are *children under fifteen years of age* some of whom cannot expect the support and care of parents, relatives or friends and therefore must be provided for in some manner by the community. There are also other children who have parents or relatives whose tangible wealth or earning power is so small that the children cannot be given the minimum attention that is commonly regarded as a social necessity. We therefore find child welfare organizations which care for dependent children and maintain day nurseries, kindergartens, and auxiliary school services.

4. Next there are many *educational problems* which, in the judgment of a large number of persons, are not receiving adequate attention from the educational agencies normally regarded as having the primary responsibilities for education. These result in the maintenance of organizations which require contributive support in order that they may give direct education to the foreign-born, may provide technical and professional training not otherwise available in sufficient quantities, maintain museums, libraries, Boy Scouts, Girl Scouts, and in some cases churches.

5. There are also important agencies which deal indirectly with the problem of maintaining health by emphasizing *recreation*. They also serve other important social purposes incidental thereto. We therefore have neighborhood houses, Y. M. C. A.'s, Y. W. C. A.'s, settlements, etc., and while each of them differs in its emphasis, all usually require some contributive support for which corporations are often approached.

6. Then there are organizations which might be termed overhead in nature because they deal primarily with the *management of the local social welfare work*. They give attention to the maintenance of common services as between the various social welfare agencies, to the coordination of effort, to the raising of money and to research. Thus there are councils of social agencies, community chests and, in some cases, foundations.

7. Finally there is a miscellaneous group of activities really conducted to raise money which in some cases is for social welfare work mainly supported otherwise, and in other cases is to support social welfare work not otherwise financed. Thus we have charity balls, police and firemen's benefit associations, souvenir programs, etc.

Then there is another aspect of the problem. It seems in order to point out that one might reasonably hold that the cost of attention to individuals or families temporarily or chronically out of gear with our economic sub-structure is often the price we must pay for weaknesses, failures or incompleteness of economic policy and therefore a proper charge against business. Whether the cost of relief is paid by production through public taxation or through private but joint agencies is of little importance in this respect. Business

pays it finally and the main difference of importance is that business sees the payment more clearly when it makes a contribution to a social welfare agency along with others than when it makes the payment through taxation in order that the work may be done by public agencies. It is usually true, however, that when local social welfare work is financed through the tax levy the cost is more widely spread over the various elements of the community.

Bases of Contribution. And now, as one more aspect of the problem, I should like to point out that the financial policy underlying local social welfare work at this time usually contemplates that contributions will be secured on one of four bases, which are (a) capacity to pay, (b) willingness to pay, (c) political pressure, and (d) sales pressure. It therefore appears that financing policies for local social welfare which result in requests for corporation contributions are still in the pale realms of shadow where they have little rational basis. The writer believes that most of these four bases for contributions at present are seriously open to question and that it is time to take steps toward the development of a rational policy.

This, however, brings us to the point where it must be recognized that there are important obstacles in the background.

Obstacles to Development of Rational Policy. Corporations tend increasingly to become national in scope and to conduct their affairs so that the activities of units in many different local communities must be controlled and coordinated. At the same time, however, it seems apparent that there is but little national-mindedness in the United States. We are still highly individualistic and but a few people are interested in establishing a more real national solidarity. This presents obstacles of prime importance. Back of any specific difference of opinion which may arise in the relations between a corporation that we may term national in scope and a local community or a local agency, is an emotional factor that stands in the way of a quick or complete understanding. Leaders in most local communities feel quite "sufficient unto themselves" in their social welfare work and to a degree that in the writer's opinion, is not warranted.

Another important obstacle is the lack of a more general understanding of science, the nature of science, and scientific methods. Many individuals will profess a desire to listen to the voice of the past in relation to a better way of meeting the problems of the present or planning to meet the problems of the future. However, when it actually comes to finding the point where their predecessors left off in their knowledge of a particular subject and trying to begin there without making the same mistakes over again, there are few indeed who have sufficient respect for accumulated experience to avoid going clear back and beginning where their predecessors began. This of course presents an obstacle of intangible nature that is of the greatest importance. A business corporation carrying on its activities in several communities finds it necessary and profitable to conform increasingly to scientific methods. There may therefore be an unconscious or subconscious clash between accumulated experience and emotional individualism, and it may occur without realization of its true nature or presence by either party.

Another obstacle in the background that is of distinct importance although related somewhat to the preceding one is that many are inconsistent enough

to clamor for liberty and complete independence at one moment and in the next reach out for the advantages of cooperation and organization with no willingness to pay what it costs. There is little realization of the essentials of group action, although it is generally recognized that there are advantages in organized cooperation. However, it is not often conceded that these advantages may be gained only at the price of conformity to essential principles which must of necessity restrict individual freedom of action somewhat. In this respect we still seem to expect to "eat our cake and have it too."

Then there is the important obstacle represented by the view that outside agencies, businesses, or corporations, take money out of the community while local businesses or agencies keep it at home. No one will question but that, within reasonable limits, there are definite economic advantages in bringing demand and supply together as near to the demand and as economically as possible. There are limits within which this can be done, however, and it is easy for misunderstanding to develop, as well as for one who takes but a superficial view to overstress the principle of keeping money at home. In studying this question from the several different points of view necessarily involved, it should become clear that it is wasting one's breath to try to prove the complete self-sufficiency of a local community in the United States. It does not seem necessary to delve deeply into our economic or social structure to see this, but if we stay in the realm of ideas alone I think it will become apparent that it is one more popular fallacy that should be exploded. The minimum necessities, simply as ideas required to maintain a community as an organized and vital force, are not entirely present within its boundaries. Assuming that ideas finally should be the basis of all action, I think it obvious that ideas generated locally, without access to a wider range of experience than that which is purely local, are seldom good enough to maintain local business and social efforts, much less improve them. This, of course, is a very large subject and one that might well have an entire paper devoted to it, but I refer to it in passing because one should note our increasing interdependence and realize that the sooner the "Main Street" point of view and the "Wall Street" point of view are intelligently adjusted to each other the better off the nation will be.

Finally there is the important obstacle represented by the lack of a rational financing policy for local social welfare work. As before mentioned, this work began with an emotional appeal. It seems clear that much of it is in transition from contributed support to a basis that is more sound from an economic point of view. Possibly the services rendered may be measured increasingly and charges made accordingly. In the meantime, however, the emotional appeal presents a real obstacle because business corporations must have good reasons for disbursing money and cannot allow emotion to sway them.

The Points of View Involved. If we move now from the classification of the problem and consideration of its background to something a little nearer, we will find that there are generally six different points of view involved:

1. There is the local general public. Its view is vague and indefinite and can be described in many ways from the standpoint of this paper. It seems, however, that it may be divided between those who are economically

self-sufficient on the one hand and those who, for various reasons, may not be. The general public is a potential rather than a real factor but is important because, once an issue of general concern is drawn, the public usually interests itself and becomes the determining factor.

2. Then there are the few capitalists and financiers who usually are the leaders not only in finance and business, but in dealing with the problems of the many who at the moment do not have stored up wealth or earning power.

3. Next there is a secondary group of leaders that we might call the local business men, who control business concerns operating as a single unit or conducting limited activities within the community, this group of leaders not being active in community affairs.

4. Then there are the local social welfare agencies which give organized attention to various social problems. These may be divided between those financed directly out of tax collections, and those financed privately by individuals and organizations chiefly through contributions.

5. Next, we have an important local factor that has developed particularly within the last four or five years in the form of community chests. These represent agencies through which the contribution requirements of local social welfare are raised cooperatively and in an organized manner.

6. Then on the other hand we have the business corporations which may be termed national in scope because they maintain important units in at least two places, and usually a great many more. Their point of view and the problem presented to them vary somewhat depending upon whether they have local retail stores, local or area sales offices, local or area wholesale distributing units, or local manufacturing plants.

To take up each of these points of view and analyze it separately, except from the standpoint of our subject, would require more time than is available. We shall therefore endeavor to consider the problem chiefly from the last point of view, *viz.*, the national corporation. When I use the term national corporation or national business corporation, it implies no sharp classification between business concerns, except that it excludes local business enterprises that have no important intercity control problem. National distribution, or widespread interstate distribution, or widespread intrastate distribution should usually provide the test as to what industrial concerns should come within its scope, and on the other hand a few or many local retail stores would provide the test for a purely distributing concern.

Therefore let us next consider briefly the corporation in comparison with the individual.

Legal Basis for Corporation Expenditures. Practice has run ahead of policy in this field, as suggested previously, and this fact is emphasized when one turns to look up the limits within which a corporation may make expenditures. The corporation is a creature of the law and its directors are in a position of trusteeship. When a management acting for a board commits a corporation to a payment, it is on questionable ground if the purpose for which the commitment is made does not clearly represent something of value or advantage to the corporation. It is my understanding that so far as the courts have gone into the matter, there has been a general willingness to leave much to the discretion of the board of directors. There is therefore a wide divergence in views, so that unless it appears that a payment is quite definitely

for some value, that sooner or later accrues to the corporation direct, or to it through its employees, the payment might be challenged on the ground that a board of directors has no power to give away stockholders' money. This of course is a technical view of the situation and may not be an entirely correct or complete presentation of its legal aspects, because the attitude of the court may vary according to the state, but one who wishes to analyze the problem more deeply will do well to consider this essential difference between a corporation and the individual. When contributions are involved it is clear, however, that the individual may indulge in philanthropy within very wide limits while it is also clear that a business corporation may only venture a short distance into what is labelled philanthropy, and then only in case it is the judgment of its board of directors that some advantage accrues to the corporation.

It becomes increasingly evident that there are many cases where the words "contribution" and "gift" are questionable if a business corporation's affairs are under consideration. Normally these words imply no direct and definite accrual of value to the contributor or giver, and their use therefore is open to question where it appears that some value accrues to the corporation. It also seems clear that if a corporation makes financial commitments towards the cost of local agencies which are really necessary to meet continuing or occasional needs of employees or their families, these might more accurately be described as (a) a payment for services rendered, (b) a premium against social contingencies that may arise, or (c) an investment to create community conditions on which a return might reasonably be expected in the future. In all of these cases a board of directors might regard the outlay as a necessary and proper expense.

Normally the cost of maintaining the minimum acceptable standard of community life is considered a proper assessment against the members of municipal corporations although the relation of a resident and citizen to his city or town is essentially different from that between stockholders and business corporations. Even though there are wide variations, however, it seems important to note that the difficulties in financing local social welfare work arise chiefly out of a difference of opinion as to the necessity, as well as the manner of meeting the cost of improvement or advancement of standards. The individual resident of a community of course has much local pride even if he may be limited in experience. He is usually much more in readiness to make outlays to advance community conditions than would be the case with a business corporation which must at all times be prepared to defend itself by showing good and sufficient reasons for its expenditures. The individual citizen is therefore willing to spend more than may be available from taxes to maintain a particular standard of community service or to raise the standard. He naturally exerts pressure on all factors in the community to join in sharing the cost of what may be described as social welfare additions and betterments, but as yet he has worked out no basis for making a reasonable apportionment of the cost.

While there is still little definite evidence on the subject, it seems logical to touch next on the kind and degree of corporation participation in the cost of local social welfare work.

Corporation Participation in Local Social Work. A corporation may not only contribute financially but it may indirectly make a contribution by permitting local representatives to occupy positions of leadership in community affairs. Next, it participates indirectly through the endorsement which may be given to a proposal or program as a means of aiding in the enlistment of interest and support to establish and develop it. Next, it may participate by making available the use of property as might be the case in the event that real estate, building or equipment are used for local social welfare purposes or on occasions. Then it could participate through a contribution of goods, as might be represented by products of the company or supplies given for local social welfare purposes either without charge or at less than the cost at which the welfare organization could obtain the same articles otherwise. Finally it might participate by making available the services of outside specialists to advise regarding a particular local social welfare problem.

Financial participation as a rule would fall somewhere within the following classification: (1) contributions for current budget, (2) contributions for special projects, (3) contributions for buildings and equipment, (4) contributions for endowment, (5) memberships from which direct advantage accrues, (6) travel and meeting expenses, and (7) periodicals and publications.

Expectations as a Participant. In connection with the consideration of requests for contributions, a corporation may often make as great a contribution through its expectations as it may make financially. While there may be many specific points of interest to which attention should be given the following tentatively suggested standards should be helpful in many cases:

1. The particular local social welfare organization for which amounts are made available is dealing with a real need and is not overlapping or duplicating the work of another efficiently managed organization.

2. The organization has the necessary minimum of equipment to conduct its work with reasonable efficiency.

3. Reasonable progress is being made in correcting the conditions from which the need for the work of the organization arises.

4. The work can be more economically and efficiently conducted under a separate organization than as a part of another organization with which it might be affiliated or consolidated, whether such a relationship has been considered or not.

5. The board of directors are responsible citizens who are generally recognized as leaders in the community and at least one-third of them give sufficient attention and time to make the board a vital and controlling factor in the work.

6. The organization has an adequate financial system, including a budget and the proper books of account and financial statements to make the budget effective as an instrument of control and has its books audited at least annually by auditors who have no part in keeping its books currently.

7. The cost of raising its contributions is not excessive.

8. The financing policy for its work results in a steady pressure to find a business basis for financing the work and for reducing the proportion of the cost that is required in the form of contributions or income from the amounts contributed.

9. There is a definite statistical system which keeps track of the work done as well as of the conditions in the field with which the organization is concerned, but does so without over-stressing unimportant items.

10. The funds of the organization are properly safeguarded and managed.

11. The purchases of the organization are managed so as to make for the most prudent outlays and in no way are controlled by considerations of profit, directly or indirectly, either for employees or members of its governing body.

12. The employed personnel are competent and are dealing with the problems of the organization in a practical way.

13. A cooperative attitude in relation to other social welfare agencies and other forces dealing with the problems of the community not only characterizes the work of the organization but is manifest to others.

It is well to hold in mind that if a corporation's payments are contributions it is in the position of principal while the beneficiary organization is in the position of agent. So far as responsibility can be placed therefore it finally rests on the principal who naturally is bound to show that all reasonable steps have been taken to establish the propriety of the participation.

Bases of Financial Participation Usually Found. The lack of a rational financing policy is evidenced quite definitely by the tendency of those enlisting support for local social welfare projects to do so on any basis that they can "get away with," and a similar tendency on the part of those dealing with the giving of corporations to restrict their contributions to the smallest possible amount. While the whole question is still very much in the realm of emotion, at least nine factors have been mentioned as bases for apportioning the cost of such work. These are: the local investment of the corporation; the number of persons employed; the value of products of the local manufacturing plant; the dollar turnover of a distributing plant; the gross sales of a retail store; the extent to which the policies and processes of a local manufacturing plant are reflected in local social welfare problems; previous contributions of the corporation or its predecessors; commercial pressure exerted on the corporation by local customers, financiers, politicians or others; and the securing of favorable publicity and the building of good will. In the writer's opinion, most of these are open to question.

Possible Scientific Basis. While it probably has not yet been done, it seems to me that it should be possible to develop a rating scale that might be used to cover each of the three main kinds of local interest of the national business corporation, *viz.*, manufacturing, wholesaling, and retailing. Before this can be worked down to individual companies, however, it would be necessary also to divide the total amount to be raised so as to determine the amount that may reasonably and legally be provided by corporations as against individuals. Little if any progress has been made in this direction as yet so that no specific suggestions as to such a division are offered at the present moment.

As an example of one method of approach to the subject after the quotas of all local manufacturing concerns had been properly determined as against those of other corporations and of individuals, the following rating scale is offered to suggest one line of attack on the problem of apportioning the

total manufacturing quota over the separate manufacturing units in the community.

RATING SCALE

	Relative weight
1. Relative percentage of local plant operation at approximately 85 per cent capacity during each of the past five years.....	25
2. Average number of employees actually employed on the last day of each month during the past year in comparison with the total average employed by other plants in the community on the same days.....	25
3. Comparative degree to which the corporation itself provides modern local facilities to aid those seeking employment and the maintenance of hospitals, clinics, nursing service, etc., for employees and their families, thus reducing the need to provide for the same services through social welfare organizations.....	20
4. Comparative degree to which the corporation itself assists employees to provide against loss of earning power through pensions, thrift plans, insurance, etc.....	15
5. Comparative effect during the past three years of conditions of work in the plant and particularly of special processes, on the physical condition of employees or other residents of the community.....	15

In the other cases, *viz.* wholesale distributing units and retail, it seems doubtful that there is any other basis upon which participation might be worked out relatively than the number of employees.

While favorable publicity and good will may enter into such a question to some extent, payments made with that consideration in view probably should be classified as selling expense and not as contributions.

Cooperation Procedure Should Be Systematic. This is a vast subject in itself and no attempt will be made to analyze it in detail at this point. If a corporation has not given organized attention to its contributions up to the present and has left such matters to individual executives, it must of course assemble its facts so that it has a complete record, in some one place, of payments made for local social welfare purposes. At the outset there must therefore be a period of survey and organization of data incidental to which important economies may often be effected. After this step is taken, the question of intermittent surveys arises, and the corporation which desires to go into the matter carefully will sooner or later find it advantageous to work out a systematic procedure to deal with all phases of the question including the method of handling contacts when requests are made, a procedure to have requests and recommendations from local officials checked at a central point, etc. There is also the problem of dealing with an original application, the question of how to handle renewals and the extent to which a corporation should allow local representatives to be active in the control of local social welfare work. Further to be considered is the use of contributions to make certain that the implied commission which the cooperation issued, by making the grant, has been executed.

It seems of the highest importance *that the national business corporation go to unusual lengths to avoid the local irritation that automatically develops when absentee control becomes too apparent or seems arbitrary.* In recent years the results of this tendency have sometimes been referred to as the controversy of "Main Street vs. Wall Street." While it may not be immediately apparent, there should be some advantage to the local community if there is the more intelligent restriction of the activity of the local business unit, which usually occurs as a result of linking it up so that it receives the benefit of outside supervision. Because there is so little real understanding of the values which flow both ways when this occurs, however, it seems of great importance that executives of national business corporations guard against a procedure which creates a feeling in a local community that "we cannot do anything without the approval of Chicago" or "we can't get it by New York." It even seems questionable if a local manager is allowed to give as the reason for not participating in some local project that "I recommended it, but Detroit won't stand for it." It seems beyond question that it is unnecessary in dealing with these matters that the out of town or overhead units in the business organization be mentioned at all. A proposal should be considered on its own merits and, as a rule, the reason for non-participation should be stated, rather than to give the impression that some remote control is probably arbitrary and acting in a high-handed manner to prevent meeting some need that a number of local people think important. The procedure of the national corporation should therefore give the most careful attention to what the local contact man does, and what he says.

Justification for Participation. A corporation national in scope or important from a regional standpoint may broadly consider that the provision of the local social welfare services commonly regarded as necessary to maintain the minimum standard of living which makes it possible to secure and hold desirable employees in a given community is the main justification for its financial participation in the cost of such activities. This does not imply that there is justification for participating financially in all local social welfare work, but that a reasonable case may be made to the effect that values accrue quite directly to the corporation as the result of work done by many of the agencies supported.

There is little or nothing to be gained by discussing justification from the standpoint of obligation, as neither practice nor policy has proceeded far enough as yet to show that there can be an obligation to make a "contribution." It seems far more important that justification be considered from the standpoint of values accruing, or services rendered, and a reconciliation of views gradually effected around that principle.

Where a purely "company town" is not involved, the business corporation, through participation with others in the joint support of local social welfare work, should gain two real advantages, viz.: there should be a better quality of social welfare work done and the cost of doing it should be less than if several additional and independent agencies were to be maintained. Moreover the business corporation, the activities of which are extended widely over many communities, is not only relieved of expense by participating in a joint effort with others but it is also relieved of a heavy burden of

responsibility that might otherwise rest more directly on it. By supporting local sponsorship and management, closer supervision and better service should be given than the national business corporation could provide if it were to attempt to meet the same needs from a distance or if the non-participation of several corporations forced provision through local tax levies to meet the cost of certain welfare work deemed necessary by local leaders.

Another justification for a business corporation's participating financially in jointly conducted local social welfare work, under private local leadership, lies in the fact that if the same work were to be maintained by local governmental agencies the cost often would be much higher. The fact that it would be higher of course might not be apparent because the cost might not be separately indicated or looked up when taxes are paid.

Under the heading of justification it is important again to refer to the fact that the whole problem is made difficult by the terms used. As previously stated, there are grounds for doubt as to whether the word contribution is properly used in respect of amounts made available for many social welfare projects. It seems clear that as soon as there is widespread recognition that a certain piece of local social welfare work has value, it is doubtful as to whether the word contribution should thereafter be used. Some observe that the word has been carried too long and it is particularly open to question if it is converted into a phrase by adding the word "voluntary." This point is made on the ground that it hardly seems reasonable to speak of one of these payments as a voluntary contribution, and also as a payment for values accrued, or services rendered, at the same time.

Another set of underlying considerations that has significance from the standpoint of justification emerges from the fact that what occurs to the employee or his family, during the two-thirds of his time that he is not at work, usually has a very direct bearing upon what he does during the one-third of his time that he is at work. The illness of the worker or the illness of his family, and the use of leisure time, can hardly be waved aside and left for casual and unintelligent treatment, if for no other reason than that the cost of dealing with the problem in that manner on a long range basis is greater than if something is done at the present time of constructive nature. Social welfare agencies concern themselves very largely with the other two-thirds of the employee's day. Moreover, it is important that a corporation having a large interest in community affairs, because it maintains a large working organization, should not hold itself aloof and leave social welfare planning too much to others. The fact that two-thirds of the time of its working force is spent outside of the control of the local management cannot be taken as justification for non-participation in the study of the problems incidental thereto and the formation of the plans. It seems far better that the corporations provide for direct representation in the making of plans than to leave this entirely to others.

Favorable publicity and community good will as a justification for financial participation of the corporation in the cost of local social welfare are somewhat open to question. Just where the fine dividing line between what is right and what is questionable falls is not yet clear. It seems reasonable to believe, however, that the extent to which publicity and good will shall

enter into a decision made with an eye to sales falls outside of the scope of this paper and presents a question of sales policy and of selling expense. If, however, participation is decided upon without an eye to possibility of sales, and without an eye to the accrual of values, or to services to be rendered, it is doubtful as to just where it leaves one. The amount would probably be charged to general expense anyway and justification found in the higher realms of policy above and beyond that of contributions.

Competitive Aspect. It also seems true that there is a competitive aspect to the justification of corporation contributions. The kind and extent of participation by a national business corporation in the cost of local social welfare are and naturally must be affected to some extent by the standard of participation set by local manufacturers or retailers in similar or competing lines. Whether it is reasonable or not, the failure of a national business corporation to participate on a basis that compared favorably with these local competitors is used against the outside corporation.

Moreover it seems true that as yet the policies of national business corporations have seldom been sufficiently defined to indicate the extent to which these outside corporations can make their local managers adequate substitutes for the local capitalists which they in some cases replace. The owner and manager of an important local industry that is taken over by an outside corporation, and the owner and manager of a large department store that is added to a national chain, usually have been quite different from the community standpoint than their successors because of the greater autonomy they naturally had in conducting the business. The national business corporation naturally will desire to build up a local representation which will compare favorably with its predecessor or his present day counterpart, which we shall here describe as the local capitalist.

The Community Chest. One of the most important developments since the war on the side of organization and management of local welfare work is the so-called community chest. There are now about 325 of these in the United States.

Local community chests present two main questions to the national business corporation. The first is the nature of and extent to which a local agent of the corporation shall participate in the social welfare work of the community and the actual work of financing it, and the second is the extent to which the corporation should finance the social welfare work included in the community chest budget.

The community chest in theory offers definite advantages, but in its present form it also presents real disadvantages. The restraining influence it exerts on the multiplication of appeals locally, however, is regarded by many as so important that the other weaknesses in the idea must be grappled with and straightened out. As a matter of fact, it may reasonably be said that the whole structure of local social welfare organization is still in the process of development, and that so far as the community chest is concerned it should have reasonable opportunity to prove itself.

Of course, from the standpoint of the corporation one of the outstanding irritations is the tendency of local leaders to exert sales pressure as a

means of forcing contributions to community chests. Competing corporations are frequently played against one another and the local leaders thus exact contributions by threatening to place orders elsewhere. A business corporation that has no reasonable policy as to participation in the cost of privately operated local social welfare cannot expect reasonable policies to be followed by local leaders. Most corporations, however, are not in this class. In the last analysis, the use of sales pressure is a hold-up method, and certainly can have no place in a rational financing policy for social welfare work. If a corporation allows it to be "put over" it is not proper to classify the resulting payment as a contribution. It should be considered selling expense. Of course the continuance of the practice will engender a corrective, but it should not be allowed to proceed to that point before it receives intelligent attention.

Another important problem, from the standpoint of the business corporation, is presented by the fact that many local social welfare projects, which vary widely in importance from the standpoint of the corporation, are financed through the budget of the community chest. The corporation may designate its contribution, but the policies followed by chests practically nullify the purpose of designation. The corporation then is confronted by real difficulties if legal restrictions are operative. Many of the projects supported by local community chests have little value and importance to the majority of business corporations, and can hardly prove that the values they create accrue very definitely to the corporation.

The community chests have a national organization known as the American Association of Community Chest Councils. This organization has recently promoted a study of the problem of national corporations in relation to the support of local social welfare, and a book presenting the results of what was largely a factual study has been published and is available from the National Bureau of Economic Research.

Taxes. A review of corporation contributions no matter how brief would hardly seem adequate if federal taxes were not mentioned. The problem here arises chiefly from the view of the federal tax authorities that they have no right to encourage generosity with other people's money. The Revenue Act of 1928 provides in Section 23 that in computing income there shall be allowed as expenses all the necessary and ordinary expenses paid or incurred during the taxable year in carrying on any trade or business.

The difficulty apparently arises because the phrase "ordinary and necessary expenses" is not defined in the law. The tax authorities question contributions made by a corporation as ordinary and necessary expenses.

No instances in which this question has been fought out with the federal tax authorities by a national corporation have yet come to our attention. It appears that as a rule the amounts involved have been relatively small, and that most of the corporations have had too much at stake in other pending tax cases to exert pressure along these lines. There has been some discussion as to ways and means of getting at the problem but as yet no definite course of action has been determined upon. If, as previously suggested, it appears that the word contribution is not correctly used and that some

value accrues to the corporation, the way out should be less difficult than it has seemed to be up to this time.

There is a statute in Ohio that authorizes Ohio corporations to cooperate with other corporations and individuals in the creation and maintenance of community funds or other philanthropic and benevolent instrumentalities conducive to public welfare. This law gives the directors power to appropriate for such purposes such sums as they may deem expedient, and as in their judgment will contribute to the protection of corporate interests, subject to the proviso that special authorization is required if and when such expenditures in any calendar year exceed 1 per cent of the corporations capital stock outstanding.

Conclusions

It seems reasonable to say (1) that a rational basis of financing local social welfare work yet remains to be developed, (2) that the contributions of corporations are described in a questionable way if the word "contribution" is used when value received in any way enters into the making of the contribution, (3) that a corporation cannot "give away" money at all, in the sense that no value accrues to it as the result of giving, (4) that a national business corporation must proceed slowly in participating in the cost of local social welfare work and that its participation must depend mainly upon the number of its employees in a local community, and to some extent the effect of its own policies within the community, (5) that a corporation is more restricted in its powers than an individual, (6) that a corporation should exert the same incidental constructive influence in connection with so-called gifts for which opportunities are open to any constructive-minded giver, (7) that the corporation should have a well defined policy with respect to contributions and such procedure as the amount of its contributions warrants, (8) that steps should be taken to reconcile the points of view of the leaders of the local money raising organizations with the national business corporation policies in the same field, (9) that there is a sound basis for many local social welfare projects, but at the same time there is much that is questionable from a corporation standpoint, (10) that sales pressure to secure corporation contributions for local social welfare is simply a hold-up method that may easily lead to reprisals, (11) that the procedure of the corporation having many local contacts should be carefully standardized so that it does not become notorious as a factor in the community that is insensitive and unresponsive to reasonable community needs, and (12) pending a more complete rationalization of practice in this field, compromises must be made as usual but that the expedient thing should be supplanted by sound policy at the earliest possible date.

Finally, it is my own impression after studying the question that on the whole the business corporations and especially those having national distribution are much more reasonable about putting money into local communities for local social welfare, regardless of whether they do all that they might do, than many local communities are about soliciting or treating contributions from corporations for these purposes.

THE SCOPE OF PUBLIC RELATIONS WORK IN INDUSTRY¹BY LEON V. QUIGLEY, *Technical Editor, Bakelite Corporation*

Modern industry, built fundamentally on research, production, and sales, has now developed an auxiliary department which coordinates with the first three in relating industry to its market or "field of force." This organized effort—interpreting and relating industry to its clients and to the general public—is designated by the term "public relations." The work embraces several distinct lines of activity, but always there are two principal standards which it is expected to meet. From the standpoint of science technical information must be unequivocally accurate; commercial effectiveness demands that it be interesting and keyed to the readers' viewpoint. Granting this twofold standard, public relations work in industry can proceed most effectively when its purpose and methods are understood and constructively criticized by the physical scientist, engineer, and economist, no less than by industrialist and commercial executive.

In citing the departments of research, production, and sales as fundamental in modern industry, we are, of course, additionally aware of the importance of finance and administration. We are assuming, however, that these factors underlie industry as a whole, and in the interest of conciseness we shall not elaborate on their function. Likewise we are mindful of numerous other departments in industry, such as purchasing, advertising, engineering service. The scope of the present paper will not permit a discussion of these several related departments. For the purpose of this *résumé*, they will be understood to be included under the three major divisions, research, production, and sales. So, too, public relations activity is related, particularly to sales. In some measure it could be classed under each one of the three fields, but in view of the scope of duties it is probably best understood when separately considered. To a limited extent public relations work can be performed, and is performed, by workers in every department of industry. In organizations of considerable size, however, the field of the activity becomes automatically so large that a separate departmental unit is assigned the task of its direction.

The work of such a department may be defined as an organized and sustained liaison effort dedicated to the task of coördinating an organization with its market or field of service. In this function it does not replace or duplicate the work of service engineering and sales, but serves rather as an auxiliary. An interesting fact is that public relations activity does not operate like sales promotion and advertising, within the scope of their correct definition. True, it is conducive to sales results, but its methods are those of mediation rather than promotion. It studies and seeks to improve the relationship between industry and its market, but it differs from advertising in the content, method, and appeal of its work, and notably in the regulation of emphasis.

The economic value of public relations work is found in the fact that it serves to relate industry to its market. Thus it participates in the develop-

¹ Including excerpts from address before the Division of Industrial and Engineering Chemistry at the National Meeting of the American Chemical Society, Atlanta, Ga., 1930.

ment, direction, maintenance, or increase of commodity interchange. Commodity interchange is usually the *raison d'être* of business, commerce, or industry.

Origin of Public Relations Work. The origin of public relations work can be traced to the older profession of law. Analogies are found in the logic of its procedure, the advisory nature of its counsel, and in the reliance it places on expert testimony. In industry the advisor in public relations is as yet less understood in his function than the corporation counsel in his legal function. This condition appears natural, however, when we realize the relative antiquity of the legal profession. Probably difficult to define was the profession of the first lawyer who stood forth to interpret the position of a client. Organized legal counsel developed only after the premise was granted that there was both justification and value in having some particular consultant designated to study the procedure of the law and to specialize in presenting the other fellow's case at court.

Like the business of law, the work we are discussing is as old as human experience. The role of the ambassador is not new. However you may regard the term "public" as descriptive of the mediation or liaison department, the word "relations" is here properly explicit. Not only does it imply the coupling of things together, but it means also the act of recounting, describing, narrating. Thus, according to definition, counsel on public relations serves both as coordinator and narrator. Public relations work, as a profession, had its industrial origin at the beginning of the present century. Its development, then, was occasioned by the effort fairly to interpret both sides of controversial situations which arose in the operation of public utilities. One senses the difference between a frantic and a temperate press at the time of coal strikes and railway labor trouble; likewise at times of regional or national economic depressions; likewise when operating regulations for public utilities are being determined or adjudicated by courts or boards representing municipalities, states, or the nation. Found useful in emergencies, when accurate interpretation was desperately needed, public relations liaison was retained to function when interpretation could be justified only as part of normal operation. From public utilities—notably, electric power, transportation, and communication companies; organizations engaged in the mining and distribution of coal and oil; and companies engaged in the packing of meat products—an interest in organized mediation and interpretation developed in the electrical manufacturing industry generally, including the producers of electrical machinery. During the past decade the organized effort of interpreting an organization to its field of force has advanced to embrace professional societies, trade associations, research foundations, as well as numerous industrial organizations, mechanical, electrical, and chemical.

Interpretation of Scientific Achievements. The value of the third party, or counsel, in interpreting the work of science and industry can best be indicated by a specific example. For instance, let us consider the case of a chemist announcing, at a meeting of the American Chemical Society, the completion of a phenomenal research achievement. We should expect this to be reported in trade journals and in the newspaper press. It is the duty of science to make its work known—for the advancement of science, for the

instruction of the profession, and for the information of the public at large. But today scientific advance is so ramified, and specialization so universal, that the average publication may be in no position to obtain a suitable account. The expert reporting of technical achievements, in divers specialized fields, can be accomplished by the magazine or newspaper, *per se*, only when it maintains a large reportorial staff of experts. For most publications this entails an expense too large to carry. Perhaps the press would omit mention of the incident in question; more likely it would publish an account which was sensational, rather than conservative; garbled and ambiguous, rather than concise and accurate. That clever, valuable, inimitable fellow known as "staff writer" is too often made to speak as one in authority, whether about pentosans or ptarmigans, Diesel engines, or television. Looking at the problem from another angle, we find that the researcher responsible for the achievement is seldom in the best position to interpret his work to the public, even though he be willing to make the attempt.

So, too, in industry. The achievement of the research department and laboratory, and of the production unit can best be interpreted by qualified witnesses who specialize in the difficult technic of interpretation. Naturally, it is to be stipulated that *ex parte* witnesses be zealous in obtaining from the actual doers of the work every morsel of evidence which will be conducive to accurate interpretation and thorough understanding. It is assumed, further, that the interpreters will be bound by standards, technical as well as literary; also that their training and experience in a given technical field will have been such as to give authority to their interpretation in that field.

At this point you may suggest that all of the work of the research department and laboratory cannot be talked about to trade journals, to the newspaper press, to clients, to the public. Likewise, it is fair to say that a portion of the work in plant and laboratory is not worth talking about. But, with complete recognition of these conditions, it is the business of the interpreter to consider all factors, and then ethically to disseminate such portions of the available information as may appear, in his judgment, to be interesting, timely, and useful. Information should be released only when it is deemed valuable to the recipient, and to the recipient no less, and in fact a bit more, than to the organization which releases it.

Standards. From these considerations we find that there are several requirements to be met. Science and engineering require, and properly, that the description of technical work be authoritative, accurate, conservative, professional. Next, commercial industry requires that the reporting of its work be accurate and constructive; further, that the report be in accord with a highly individualized, though ramified entity, called policy. Industry stipulates, also, that public relations activity, like other departments, be justified economically as contributing to the *raison d'être* of the particular business of the industry. Finally, the clientele, or the public, requires that the interpretation of technical work be correct, interesting, or advantageous to them—in general, it must be worthy of their attention.

Reviewing the standards imposed upon technical public relations work, and understanding its place and relative importance in industry, we see that it is a subject in which men of science may be expected to be increasingly interested.

Their interest and cooperation, manifested by criticism and suggestion, are indispensable. More than upon any other factor, successful furtherance of public relations work in industry depends upon the intelligent cooperation of physical scientists, engineers, and economists.

Classification of Public Relations Work. Industrial public relations work can be classified into six or eight major branches. The comprehensive program outlined below embraces activities which are variously described as technical publicity, press bureau, educational service, news service, etc.

1. Furnishing technical information to the trade journal and newspaper press, particularly at their request, and in line with established journalistic and technical standards.

2. Cooperation with authors, editors, and lecturers who request informational summaries of an industry or data on some phase of its specialized operation and policy.

3. Preparation of bulletins and institutional literature of a technical nature—involving compilation of data, preparation of text, and selection and captioning of illustrations. This form of manufacturers' literature is devised, not as a general advertising message to customers or potential customers, but rather as technical literature. It may be designed for specific groups—engineers, scientists, students, the public.

4. Cooperation with personnel of industry, by assisting in their preparation of papers and articles for presentation to the professional societies.

5. Cooperation with innumerable organizations and individuals (classifiable as miscellaneous). Their first contact with an industry may, or may not, warrant transference to the other departments, such as research, production, and sales. This heading includes the maintenance of a general information bureau.

6. Preparation and presentation of public addresses; participation in work of professional societies, trade associations, etc.

7. Educational service. This involves the dissemination of information to universities, colleges, and schools; the devising of exhibits, pictorial services, motion-picture films, etc.; also the furnishing of advices for theses and for student projects.

8. Observation and study of the trend of news events, generally, with a view to cooperation with the press in guiding public attention authoritatively to particular science aspects thereof. For instance, the public relations counsel of a company producing helium would be useful to the press and valuable to his company by reason of his being informed on current dirigible flights. Valuable also would be his technical knowledge—of chemistry and physics generally, and of the properties, and isolation problems, of the rare gases specifically.

A subject of especial interest is the field of educational service by industry. Industry meets education along many avenues, but particularly in the transfer of education's product to adult employee status. It is apparent that there must be a liaison of interest between the two fields. Likewise, it is assumed that cooperation by the industrialist is to be responsive to the invitation of the educator. In other words, cooperation is to be along lines which have been approved by educators as sound, ethical, and valuable in the work of the classroom.

But now one may suggest that, in order to justify the maintenance of educational service by industry, the program must be made reciprocally valuable. True, but this reciprocal value to industry must be entirely secondary, and incidental to the primary purpose of education. Whatever is furnished by industry to the schools and colleges—text material, information, or consultation—has properly as its dominant purpose scientifically and conservatively to inform.

Education, and each of the other seven topics enumerated, could profitably be made the subject of a separate treatise. It is the purpose of this discussion to present a concise and balanced introduction to the program of public relations as a whole.

Principles of Procedure. Evidence has been offered to show that public relations activity, as a department of modern technical industry, is properly conducted according to principles of procedure which are sound from the engineering viewpoint. What are these principles? First, reason for the work must be surmised to exist. Second, a logical purpose of the work must be established. Third, the principal subdivisions of the work must be determined; this involves establishment of limits or defining the field of operation. Fourth, all important relevant factors must be listed and appraised. Fifth, the relativity and related importance of these factors must be accurately determined. Sixth, as the locus of field limit broadens, coherence and unity of the principal purpose must remain paramount. Seventh, the central purpose of the work must be in focus from the viewpoint of engineering and science, impersonally, as well as within the focus of the interested industry.

The sequence of this procedure is analogous to the deductive and inductive methods which underlie the logical advance of laboratory and plant work in any technical field. It suggests the engineering maxim of "getting all the facts and then proceeding." Conducted in line with such principles of engineering procedure, public relations work relies on the cooperative interest and support of those engaged in the more operational technical phases of the research department, the laboratory, and the plant. Benefiting from the constructive criticism of economists and physical scientists it will proceed to do its best work, as an adjunct to production and sales, and as a copartner of research, which is the nucleus of the industrial future.

Conclusion

By review of the points we have cited, the subject of public relations activity is doubtless now clearer in mind. We see that the subject is specialized; further, that it does not supplant or duplicate the aim and function of other departments of industry whose designations, because older, are better known. In defining the role of public relations departmental work in industry, you will recall that its prime function is that of interpretation and adjustment. Present-day industry is characterized by market complexities and by rapid transitions of process, of product, and of product application. Because of the importance and prevalence of these factors, research has come to be recognized as the safeguard of industry. In further recognition of these characteristics,

specialized departments are delegated to coordinate, continuously, the viewpoint of an industry, and its reason for existence, with the requirements and interests of the clientele and public which it is in business to serve.

You may not agree with Abraham Lincoln that public sentiment is everything. Lincoln went further to say that "with public sentiment nothing can fail, without it nothing can succeed." You may say, for instance, that there are industries which do not concern the public at all. While exceptions to any such statement can undoubtedly be found, the fact should be granted that the value of coordination between certain industries and the lay public is a minimum compared to an indispensable maximum for others. But in considering the function of public relations work in industry, we do not mean that the field of contact is, necessarily, the millions of men on the street. The public of an industry may involve principally the general public, or the industry's clientele, or both.

Abundantly granted is the fact that the future of industry is governed by the vigilance and extent of its research. Research, to do its best work in safeguarding industry, requires interested support. The conviction that research departments and laboratories are valuable, and the guarantee of their maintenance by the "patient money," of which John Teeple speaks, is based on interest in the results, understanding of the method, and confidence in the value of research achievement. Public relations work whose business it is to inform, to interpret, and to enlist cooperative interest, fulfils, therefore, a fundamental function in industry.

FUNDAMENTALS OF COMPANY PUBLICITY

BY RICHARD D. HEBB, *Public Relations Department, Swift & Company*

The man or corporation, who seeks publicity with the idea of getting free advertising, is making a serious mistake. Publicity is not intended to sell goods. Paid advertising in one form or another will help to do that.

Publicity has an entirely different function, yet it bears directly on the selling problem, in that it is intended as a *builder of confidence*. For example, how far would the small country bank get if it lacked the goodwill and confidence of the countryside?

The chief function of corporate publicity is to place the ideas and the ideals of the corporation in an understandable way before the public. The average newspaper reporter, entirely lacking in business training, ignorant of the workings of the business mind, intent only on one thing, to get the best and the biggest story for his paper, seeks to translate the facts which he secures so that they will be readable, so that they will bring out the things in which he knows the readers of his paper will be interested. He wants facts, and he does his utmost to obtain them, and to have his notes accurate; but his first duty is to his paper, not to the business man, and the manner of presentation of what he secures will not necessarily be to the liking of the man from whom he secures them. So business needs trained men to write its news so that it may be protected, at the same time seeing that the public is fully advised of its doings.

Who Is "The Public"? No discussion of corporation publicity could even approach adequacy were we not to look first at whom the publicity is to be directed. This country, the most prosperous one in the world, as our politicians, business men and bankers tell us, is first of all a nation of wage workers. Its standard of value is the wage rate per hour, or the salary per week, per month, or per year.

There is a subconscious resentment in the minds of most workers to the idea of profits earned by some one from the labors of the many. Right there we have one reason at least for intelligent publicity.

This is a big country, and it takes large scale production to feed it, to clothe and house it, to provide it transportation, amusement, luxuries and the thousand and one necessities as well as the unnecessaries that have come to be regarded as so needful. Yet large-scale production must have earnings if it is to continue. To secure iron ore from the mines along Lake Superior, transport it in boats to the lower end of Lake Michigan, resolve it into steel bars, ship those steel bars to Detroit, shape them into automobile chassis and bodies, motors and springs, to bring rubber from overseas, glass from other factories, and the other fittings, and turn out an automobile requires an immense amount of money before the first man can be given a job to do the first bit of work required. But that first man may be the first one to kick when he reads that the iron mine, and the transport lines, and the various factories all made profits from it. "I dug the ore, and the profits should belong to me because there would have been no automobile if I had not done so," is his specious argument.

Yet a simple explanation would help to change his views. What was the investment before he could get the job? If the corporations told him that they had to hire their money and that the money had to earn its wages and had to receive its wages or it would leave its job and then the worker's job would be gone, the corporation might have an easier time. But one company doing that cannot go far, can do little else, in fact, than to convince its own workers of the story.

Publicize a Person, Not a Corporation. Should a corporation seek publicity, or should it endeavor to go its own way paying no heed to the world outside its own group of shareholders?

The answer to that, of course, lies within the company. There are corporations, and hundreds of them, which flourish without publicity. In the minds of the directors of others, public relations departments are an unnecessary evil. But, if a company, dealing directly or indirectly with the public, and with which the public may feel that it is familiar, wishes to assure itself of a proper understanding of what it seeks to do, it needs and should have a properly organized public relations department.

It is an extremely difficult and well nigh impossible thing to publicize a corporation as such. We, as a part of the great American public, are not interested in the Ford Motor Company. But we are eager to know whether Henry Ford is working on a new Model B. And Henry Ford knows just that—so little is heard of the Ford Motor Company, and much of Mr. Ford and his doings.

Some executive in the company, the higher the better, should become the official mouthpiece, and such stories or statements as are given out should come from him. A story that "The Ford Motor Company announces" belongs in the advertising columns, but "Henry Ford today said," goes on page one. There are, naturally, exceptions to this, but they are not many, and each one presents its problems which must be solved.

As a matter of fact, there are as many problems as there are publicity stories, and almost as many types of publicity as there are stories. If the annual report of the company is to be made public, the thing to consider, for example, is—just what phase of the report is it desired to bring to public attention? Then center attention on that by sending with the report excerpts from the president's address featuring that phase.

Sometimes a story may be told better in motion picture than in words; stereopticon slides lend themselves for similar purposes, especially in an educational way. Public speakers, sometimes hired, at other times company executives with a good stage presence and a knowledge of their subjects, may be used to advantage, either before specialized groups, if the subject under discussion is a specialized one, or on the radio, although in the latter case the talks should be first drawn, and then quartered as to time, because our radio public has a habit of tuning out dry speeches.

Institutional advertising also is a function of public relations work, and a most important one. Institutional advertisements are read, if they are properly prepared.

One such campaign started because of an investigation of an industry. The hearings were entirely *ex parte*, and also voluminous—so much the latter that the larger press associations announced that they would carry only news developed by the investigation, and nothing else. In order that the company's side of the investigation might reach the public, paid space was taken in newspapers, in magazines and special trade publications. The campaign was nation wide, at one time eleven thousand daily and weekly newspapers being used. The chief point of attack was answered with incontrovertible facts, and answered promptly and effectively. Proof that the paid publicity was read was soon apparent; editorials began to appear slowly at first and then later more freely, in which were paragraphs directly traceable to the advertising.

The company which feels it needs publicity, and where no company official is willing to become the publicized person, will find the most satisfactory answer to its problem in institutional advertising, and more in the mechanical motion picture and stereopticon than in the news story.

In that statement I write as the former occupant of the city desk of a great daily newspaper. If people could look into the mind of the man forced to open the envelopes that come to his desk, they would hesitate to send him a letter. Fortunately for the city editors of the larger papers, the city desk sees comparatively little because in their efforts to "get to the top" many public relations experts address their mail to the managing editor, and his wastebasket is larger than that of the city desk.

The managing editor gets recipes for using baking powder that might have been read had they been addressed to the editor of the woman's page.

He learns of a second or third or fourth Jack Dempsey who needs only a little publicity to be greater than the first, he is invited to a private exhibit of water colors by an unknown artist, he is asked to take tea with the most recent Wampas of the movies. Some of this he passes on to the sports department, the art editor, or the motion picture critic, but most of it goes into his wastebasket and a large part goes there because of poor direction and lack of thought on the part of the public relations department.

News for the newspaper, should be directed to that section of the paper to which it must find its way if it is to be used. If it is to be used, it must have news value, which, after all, is what we read a paper for.

Timeliness of Material. In addition to knowing to what department of the paper certain publicity should be addressed, it also is imperative that the public relations department should, insofar as possible, time its release with reference to heavy and light news days. The story which might properly belong on a financial page, for example, would have a much more cordial reception were it released over the Good Friday holiday which prevailed in the stock markets this year. The newspapers had Friday evening, Saturday morning and evening, and Sunday and Monday mornings, when there were no markets. Financial editors at such times are glad to get copy that has legitimate news value.

One such release was a story of about 250 words. It was not only given a cordial reception by the local papers but was carried in full by two press associations, which means that it went to the 2,400 daily papers of one and to 1,400 dailies of another. Indications at this time are that it was very widely used by the papers receiving it. Normally Friday is a poor day for a release, because Friday papers, especially in the larger centers, are what is technically known as "tight" papers, with little space, due to heavy advertising. Saturday and Monday, on the other hand, are usually pretty good days.

Publicity Must Be News. In considering publicity stories, we should look at them not from the standpoint of the company which wants them sent out but from the side of the reading public. That public has not one iota of interest in an individual concern and its doings except insofar as it and its acts affect the public's daily life. The politician knows that; he is a psychologist or he would not be a politician. If what one has to say interests me as a newspaper reader, I will read it, but I will not look at it unless it does.

The city editor of a daily newspaper has the job of merchandising the most intangible and perishable thing in the world—news. It is a commodity when it happens, and not even fit for storage if not sold at once. So be sure that your offering is fresh, that it has a bearing on the reader's daily life and that you do not pick a day when the president is sending a 20,000 word message to Congress, and then maybe it will have a chance to be printed.

The city desk is becoming more alive to the fact that business makes the wheels of the country go around. Newspapers are becoming more friendly toward business stories, but the change is slow. In some isolated instances like the *New York Times* and in a less direct way some of the other larger papers, the editorial staff recognizes the business story as a constructive force, but it must have news value to be used. Mere puffery gets nowhere. The fact that a new food product has been developed has no news value; its place

is in the advertising columns. But the fact that a new method of merchandising an old product, whereby for the first time the housewife has a guarantee of quality, may have direct news value, but its news value will lie in a specific part of the paper. If sent to the city editor, it would rightfully go into the wastebasket; it does not belong in his columns. But it has a definite place on the woman's page of any publication large enough to have a woman's page.

Sometimes it is politic to send some of the new product with a story. Care must be taken, however, that the material is not overshadowed in doing so. In one instance of that kind, a perishable product was sent to the food editors of a restricted list of publications. These products were packed with dry ice, and it so happened that while the product itself was quite familiar to the writers to whom it was sent, none of them ever had seen dry ice before. This product of another concern received most of the attention.

The city desk has a reasonable interest in anything that pertains to the development of the city. Whether it is new buildings, new industries, or new jobs, it has a direct concern in any statement on the public welfare of any citizen prominent enough to warrant his being quoted. It has a direct concern in the city's charities. It is interested in fact in progress, but it has no interest in a new kind of fly paper or in any product, as such.

There is a difference, of course, in what the daily newspaper and what the trade press want and what they will use. As a matter of fact, there is a very decided difference between daily newspapers, the trade press, farm papers, and magazines of general or special circulation. Each must be considered from the angle of the clientele it serves. The trade press is interested in the industry itself, in what a particular corporation may be doing to better the industry. It is interested in the development of new processes, also in the men who work on such developments. It wants to know of their goings and comings, of their aims and how they hope to achieve them.

Viewpoint of the Reader. In the preparation of any publicity material, in my opinion, the chief thing that has to be considered is the viewpoint not of the company for which the material is being prepared but the viewpoint of the reader it is hoped to reach.

Everyone is more or less familiar with radio programs. In many of the successful programs, the advertiser buys sponsored time, pays for thirty minutes, and of that thirty minutes he gets at the most on the average of not more than three minutes. In other words, ninety per cent of the time for which he pays is given to the entertainment of the radio listener and ten per cent is devoted to a discussion of the advertiser and what he has to offer. The man who pays for radio pays for it on that basis quite cheerfully; yet the same man, preparing a publicity story which he hopes to have printed without charge in one or more publications, will insist—if he is not familiar with public relations methods—that his company and his product be plastered all over the story. It is safe to adopt the radio rule of one-tenth or less of the story for the man who thinks he has a story to tell and ninety per cent or more reader interest.

If publicity is prepared from the standpoint of the corporation and not from the standpoint of the reader, it will not get far, except in the case of weaker publications which hope that by using such puffery they may share in

any advertising which may follow. The board of directors may like it better, but if it is not printed, not much good has been done.

It takes a trained nose for news to do intelligent publicity, but it also takes something more than that. I recall one man who worked with me at one time who had one of the best noses for news and feature stories I ever beheld. His nostrils would quiver at the slightest provocation, but he had absolutely no conception of business fundamentals or of business policies.

If he found a news story on the plant, he was after it hot foot, turned in a very good story, but one which frequently was impossible of use from the standpoint of the company because it might disclose a trade secret or run counter to company policy. He was impatient, particularly with the latter feature of his job, his attitude being "to hell with company policy, it's a good story."

It is comparatively easy to hire writers of publicity, but the mere writing is the least of the problem; getting it printed is another matter. As a matter of fact, quite a percentage of publicity today is not prepared in advance, story leads being given instead to the editors, these being followed up by men from the publication itself. There is a little matter of psychology involved, in that a "hand-out" of copy never gets the same consideration on the desk as a piece of copy prepared by a member of the staff.

Training for Publicity Man. If newspapers are to be the chief source from which publicity is sought, the man who handles the public relations work should by all means have had newspaper training, not merely on the street as a reporter but he should have had considerable desk experience in the handling of copy and the steering of news after it is inside the organization. The average reporter is good at picking up a story, but the average reporter in many cases does not know what happens to his story after it is in his own office.

One of the most successful publicity men never prepares a story more than 300 words long, and usually 150 or 200 words will get over what he has to tell. The reason is that the average publication has no trouble in getting leading articles but that sometimes filler material or miscellany required to fill the ends of columns may be scarce, and his brief publicity articles have a very good chance of being set and sent to the bank for use in just such emergency.

A man, to do publicity for a corporation, need have little or no special training in the industry for which he is to do the work. He must have business sense, but the farther away he keeps from the technical side of the industry which he is to represent and the closer he keeps in touch with the public, the better will be his results. The experts in the business, if they cooperate with him, will furnish all the technical information, and he will use his knowledge of the public to take that information and prepare it so that the public will accept it as news.

There should be a very close coordination between the advertising and public relations departments, but there should not be control of public relations by advertising. The mind of the advertising man properly runs toward its own subject—advertising. In saying this I am expressing views which are in direct opposition to those held by many. Many who have public relations departments operated in connection with and under the jurisdic-

tion of advertising departments have been and are very successful. Admitting all that, I repeat that the public relations end of the business will better serve its employer if it is run in close cooperation with the advertising department but as a separate and distinct department of the business.

Several highly successful public relations departments are operated with a minimum of supervision. In a number of instances, a public relations man has the title of assistant to the president and works closely with that executive. Thus when he wants material, he has sufficient authority by virtue of his position to get it with little question from the departments involved. After his material is prepared for publication, it usually is submitted to the head of the department from which it was obtained and if satisfactory to him as to fact only, it is o.k.'d by the president for policy and is then ready for publication. Other organizations have public relations committees which operate very successfully. The fewer people who have to do with the copy after it is prepared, the better will be that copy because most of us feel that we are pretty good writers. It is a skillful copy reader who can handle a piece of copy with a minimum of change. The poorer the copy reader, the more changes.

Handling Adverse Comment. One of the fundamentals of publicity is the handling of adverse comment. The best and simplest way to control it is to control it at the source, to seek out in advance things which might be adversely commented on, and strive to have them remedied before they become public. Publicity can be directed; for example, in the case of fire, or strike, or some similar subject.

An instance of a fire may be cited. It was a 5-11 alarm, apparatus from all parts of the city in which the plant was located being called. The public relations department covered the fire and promptly telephoned all of the facts to the City News Bureau, which sent them to the various papers. The result was a story which was not overplayed and which gave assurance that production in that plant was not interfered with in any way by the fire. An attempt to cover up the facts would have resulted in an overplay written in a more or less unfriendly fashion.

In the case of labor trouble, arrangements should be made to see that the newspapers are supplied with the facts. If the facts hurt the company, then those facts they should be met frankly and acknowledged, because they will come from the other side if it is not done and come out in a more damaging way.

It used to be the fashion on railroads in the case of a wreck to hide the facts as much as possible. I recall as a reporter in Kansas City, Missouri, covering a wreck one Sunday night. We had such facts as could be gotten on a night when there was no telegraph operator at the way station where the wreck occurred. We learned that a train loaded with injured was on its way to the city. When it arrived, reporters from the various papers in Kansas City were on hand. I was one of them. The claim agents of the road climbed off the train first and attempted to shoo us off the platform; we did not shoo, so they literally booted us out of the station, refusing all facts. The result was that I paid \$5 to an interne who was riding on one of the ambulances for the use of his coat and rode in the ambulance with two of the injured, securing from them most harrowing eye-witness stories. The paper for which I worked

played that story for more than two columns where, as a matter of fact, it was not worth more than a half column at the most. That is human nature.

I recall the attitude of a certain city desk toward certain railroads at one time. One of the roads when it had an accident would do its utmost to cover up the facts, with the result that such strenuous efforts were made to get the story that it was sometimes overplayed, and nearly always found a big headline. Another road, if it had an accident, would beat the press association into the newspaper offices with the story. Its statement would be terse but clear, and there would be a list of dead and injured if there were dead and injured in the accident. The result was that that railroad got much better consideration than the one which attempted to cover up.

Another instance of that kind deals with an explosion in a large mill. Reporters and photographers were sent to the site and were thrown out of the enclosure and thrown off the company property. They were refused permission to see any executive of the company, and the executives refused to issue a statement of any description. There had been deaths and the coroner's assistants were on the scene, and from the police and these men such facts were secured as they had. The coroner's figures of the dead and injured were taken and the story printed. In passing I may say that all the lurid details possible were given to the story by the reporters who had been handled rather roughly.

The day after the story, an executive of the corporation appeared in the city editor's office of one newspaper and demanded a correction on the story, saying it was all wrong. The city editor listened to him and asked him what the real facts were. "The real facts are our private business," was the reply, "but your statements were wrong, and I demand a retraction." The gentleman was told that he might leave the office peaceably and not return until he was prepared to give the facts on which he based his statement that the story was wrong. That is not public relations, yet there are many corporations which attempt to do business with the newspapers in just that way.

Desirability of Direct Contact. Wherever possible, a better understanding between business and the newspaper is best secured by direct contact. So much publicity, however, is being sought today that publicity men are sending out reams of copy. Professional publicists send out, in some instances, clip sheets containing stories not only for one client but for several, and in many cases are getting some results. Such publicists and their clients also are coming in for most beautiful lambastings at the hands of editorial associations and editorial magazines.

One of the chief subjects of discussion at editorial meetings is publicity and how to avoid it. An ideal set-up in a corporation would be the organization of a public relations department and contacts with news sources developed which would bring out that the public relations department was organized not for the purpose of securing publicity, but for the purpose of having centered in the department all the news sources within the corporation so that at any time a publication desired news of the industry, it could be secured quickly and accurately.

One public relations department has sent out so little real publicity material and has built for itself the reputation of furnishing news when it does send anything out, that certain press associations and certain editors look to it for news of its industry. There have been instances where stories derogatory to that particular industry have been held until the industry's answer was ready to ride with the original story. That in itself is of incalculable value because once a story is printed, it never is possible to catch up with it and overcome the lead which it has attained.

News is news today and dead material tomorrow, whether it is advantageous fact or denial. If direct contacts can be made, they should be, because frequently corporations are visualized to the outsider through the employee who is known. If that employee is a pleasant, four-square, straight-shooting individual, and liked, then the company also is liked.

Handling News Releases. There are several methods of handling news releases. If the story is of national interest, it may be released through the local office of the press associations, after also having been given to the local newspapers. A "hold for release" notice with the time set, being sure on a national release to specify whether it is Eastern Time, Western Time, or just what hour is meant, is all that is necessary to keep a story from premature publication. It is well to recognize that at the present time all of the great press associations send out material by mail in order to decrease their wire charges. Stories to be sent in this way should be sent as far ahead as possible. Usually, if they are good stories, they will get a better ride if sent in this way—by mail—because mail is cheaper than telegraph, and the editors of press associations have a certain friendly feeling for the man who thus helps them to keep down costs. There need be no hesitancy in trusting facts for future release to any reputable publication or news association.

In the case of financial releases, such as annual reports and similar statements, there are other news sources than the public press that should be recognized—ticker services, special financial publications, special trade journals, all should be covered. These news releases should go far enough ahead to provide time for adequate handling. This is a convenience to the publication and also is a matter of insurance for the company, as hasty handling increases the chance of error.

There are certain things to be borne in mind in any news release. Newspaper stories start with the climax and then go to the detail and facts. Magazine articles are just the reverse, building up the facts to the climax. Radio announcements are a climax only.

Reports on Publicity Work. One phase of the question which usually gets little consideration is—shall the publicity man make written reports on his work? It is easily answered—no.

Boards of directors like to know what is being done for the money they spend, but publicity men, as well as department heads, in making reports, are too prone to give credit to themselves for virtues which they do not possess. There have been instances of this in the not too dim past in public relations work, where publicity men have written of their dear friend, Editor So-and-So, who is "eating out of my hand," and where intimate little reports of this nature have found their way into the public print, to the undoubted embar-

rasement of Editor So-and-So and to the confounding of the publicist. There is no doubt that Editor So-and-So is more apt to bite the hand of the publicity man than eat out of it the next time they meet.

In summing up the work of the public relations department, there is only one thing that counts and that is accomplishment. It can be shown by clippings and not by reports of the friendliness of this editor or that for the publicist. The public relations department that is not in good enough standing with its own organization so that it can make oral reports does not deserve to exist.

Intracompany Publicity. An important phase of publicity is intracompany publicity relations. If a company's employees are not sold on the company itself, then the publicity will lack much of its effectiveness. It is well to remember that every employee, whether he be office boy, truck pusher, barrel roller or whatnot, is a finger of the company reaching out into the neighborhood in which that employee lives. If that finger is an unhealthy, sore one, it will spread infection, whereas if it is a healthy, clean finger, it will do helpful work.

The Branch Manager, a Goodwill Ambassador in the Community. One important factor in the translation of business to the public and one that sometimes may be overlooked, is the development of a branch manager as a goodwill ambassador in his community. There is a growing tendency at the present time for communities to develop "trade at home" slogans. The manager of a branch plant in such a town is a local man. As a rule he is a permanent resident, maintaining a home, sometimes owning one, paying taxes, belonging to the local organizations, and taking part in the life of the place in which he lives. He employs local people, has a pay roll, frequently buys considerable material there. In fact, he is bringing much money into the town life. But if he does not watch his step, he may remain an outlander for all that.

He can, tactfully, call attention to the things which he is doing for his community. To the fact that he is in fact "home folks," and thus help to build up a demand for more homemade goods.

The fact that a national organization may have branch plants is, in fact, one means of developing favorable publicity. In buying local labor and local materials for manufacture and then selling then nationally a concern opens nation-wide markets for a local commodity, and is thus able to pay prices based on national demand rather than merely local. And this sometimes is news. A carload of goods manufactured in a small town and shipped to some distant point is always an item of news for the local paper.

Corporation Publicity Is Growing. It will continue to grow if it is intelligently directed, because the public is wakening now to the fact that upon the prosperity of business depends their own prosperity. They are developing a more or less intelligent interest in business as such, but the intelligent translators of business at the present time are too pitifully few.

 field of office, 743-748
 financial, 332-347
 forms as tool of, 944-945
 from a distance, bonuses, 1495-1496
 control through reports, 1491-1493
 coordination and supervision of mills, 1493-1494
 detecting reason for decreased output, 1488-1490
 eliminating unnecessary reports, 1494-1495
 exception principle, 1490-1491
 managing director, 1496
 use of standards, 1493
 "functions" defined, 1477, 1505-1506
 importance of training policy, 1241
 increased study of, 471-472
 keeping in touch with machine changes, 580
 by line and staff organization, 1475-1478
 by removing obstacles, 974-975, 977-979
 maintaining flexibility, inventory, 1529
 investments in machines, 1529
 organization structure, 1529
 personnel, 1529
 498,
 more difficult with greater development, 1167-1168
 motives in using employee representation, 1439
- Management, non-financial incentives, value to, 1168, 1181
 office manager, duties, 932-933
 operating obligations, administration, 1476-1477
 planning and results control, 1477-1478, 1482-1483
 planning and scheduling office work, 964-974
 policy as to women supervisors, 1214-1215
 policy on mutual benefit associations, 1291-1294
 policy questions on pension plan, 1336
 policy toward trade unions, 1421
 position of the, in corporations, 381
 post-war increase in efficiency, 431
 principles of, centralized control, 1467
 delegation of authority, 1466, 1488
 directors represent stockholders, 1467
 exception principle, 1490-1491
 owners' welfare central motive, 1467
 responsibility of executives, 1466, 1488
 problems on training program, 1235-1237
 promotion policy and training, 1230-1231, 1236-1237
 regularization, 1531-1536
 research, need for, 1600-1601
 possible topics for, 1601-1602
 responsibility, to corporation, 384-385, 387-390
 for insurance, 517
 for older workers, 1310, 1315-1317, 1320
 for workers' health, 826-828
 salary administration and promotion, 855-881
 scientific, pioneers in, 1569-1570
 showing up surplus time, 924
 size and efficiency not related, 919-920
 specialization, vs. exceptions, 920-921
 vs. small independent units, 921-923
 success factors in business, 1545
 supervisory vs. personal work, 926-927
 technique to meet change, 1510-1530
 changes due to customer, 1515-1517
 changes in economic conditions, 1515
 deciding on adjustments to make, 1530
 determining where changes will occur, 1513-1515
 fact-founded operating organization, 1512-1525
 forecasting and anticipating changes, 1525-1528
 new phases of competition, 1517-1518
 provision for use of information, 1522-1525
 sources of information on changes, 1518-1522

- Manuals, for export salesmen, 316
 for filing, 936-940
 of procedure, aid to consolidated companies, 813
 distribution and check-up, 817-818
 editing, 816-817
 job analysis for, 814
 kinds of, 815-816, 818-819
 number of copies, 817
 for planning department, 971
 process of preparing, 816-818
 second edition, 817
 staff help in preparing, 813-814, 815, 816, 818
 uses of, 813, 818-819
 sales, 201-206
- Manufacturer, effect of chain stores on, 307-308
- Manufacturing division, assigning authority, 543-544
 coordinating departments of, 545-546
 defining policies, 544
 defining responsibilities, 542-543
 determining the activities, 541
 establishing the, 541-545
 grouping the functions, 541-542
 layout of departments, 545
 organization charts, 544
 organization of, 540-547
 relation to other divisions, 546-547
 selection of personnel, 544
 type of organization, 541
- Market, factor in plant location, 549
- Market information, danger of coding in advance, 20
 kinds of, to be secured from consumer, 16-18
 to be secured from jobber, 28
 to be secured from retailer, 26-27
 means for gathering, 29-30
 representative, how secured, 20
 sources, 5
- Market manager, definition, 4
 information needed, 4
- Market research and analysis, as service to salesmen, 221-222
 basic for choice of marketing channels, 103-110, 315
 common market indexes, use of, 11-12
 company records, use of, 11-12
 for export trade, 315
 factors in sale and consumption, check list, 14-15
 freezing survey results in advance, 19-20
 getting data from own organization, 10
 getting information from consumer, 16-24
 getting information from jobber, 28-29
 getting information from retailer, 24-28
 internal study of the company, 10-15
- Market research and analysis, keeping in touch with major factors, 30-36
 changing consumer, 34-35
 price, 32-33
 style, 33-34
 personal bias of investigators, 21
 preliminary field study, 15-16
 sample report on an industry, 6-10
 sample sales analysis, 11-13
 study of baking industry, 6-10
 studying from outside the company, 15-30
 studying the industry, 5-10
 system of sales territories, 35-36
 technique of interview, 22-24, 27-28
 type of investigator needed, 5
 use of mail questionnaire, 29-30
- Marketing, choice of channels, 102-126
 choice of intermediate channels, 116-126
 by company's own salesmen, 117-119
 to consumer 118
 to retailer, 118-119
 to wholesaler, 119
 consignment selling, 120-124
 contract with sales agent or factor, 119-120
 effect of chain stores on, 307-308
 export management, 310-323
 increasing competition in, 125
 of industrial goods, 121-124
 large-scale buying, growth of, 125-126
 maps of industrial markets in U. S., 121-123
 potential customers the starting point, 103-110, 126
 probability curves of demand, 105-107
 so-called revolution in, 124-126
 steps in choosing channels, 107-110
 technical research correlated with, 589, 592
 through brokers, 120
 trends in, 124-126
 types of retailing and markets served, 110-116
 (*See also* Merchandising; Sales.)
- Marketing costs (*see* Costs).
- Marketing instruments, compared, 44-47
- Mass production, beginnings of, 534-535
 effect of Taylor's work, 535
 importance of inspection, 673
 importance of measuring devices, 535
 job mass production, 534, 537
 layout for, 569, 572
 limited in application, 531, 536, 537
 misapplication of, 537-538
 single-purpose machines, 535-536, 545
 use of straight time payment in, 652
- Material, effect of changes in, 1517-1518
 flexibility of investment in, 1529

- Material, handling, assembly, 585
 - conveyors, 584-585
 - devices, 583-584
 - inter-department, 574
 - between operations, 584
 - problems, 583
 - reduce to minimum, 583
- inspection of, 674-675
- layout for flow of, 571-572, 573-574
- planning and controlling, 615-616
- raw, as factor in plant location, 549
- shapes for secondary flow of, 573-574
- standard costs, 685
- Measurement, accuracy increased, 674, 679
- of advertising effects, 53-67
- of office output, basis of incentive plan, 903-904, 924, 927-929
 - conclusions from survey of, 911
 - illustration of, 796-797
 - importance of standards, 882-883
 - makes supervisors think of costs, 929-930
 - operating cycle, 905
- procedure and time study sheets,
 - addressing machines, 907-908
 - duplicating machines, 910
 - stencil or plate cutting, 908-909
 - typists and transcribers, 905-906
- quality standards, 882-883
- shows up surplus time, 924
- studies in output, addressing machine operators, 913, 914-915
 - duplicating machine operators, 911, 913
 - stencil cutters, 917-918
 - transcribing machine operators, 911, 912
 - typists, 916, 917
- units, accounting, 887
 - addressograph, 898
 - billing machine, 901-902
 - clerical and statistical, 886-887
 - correspondence and typing, 885-886
 - difficulty in determining, 904-905
 - ditto, 900-901
 - flexotype, 898-899
 - graphotype, 897-898
 - handling papers, 884
 - Hooven typewriters, 901
 - on machines, 896-902
 - mimeograph, 900
 - multigraph, 899-900
 - procedure to determine, 896-897
 - use in supervision, 887-888, 895, 924, 929-930, 967-968
 - vs. rating scales, 926
- of performance, basic for incentive plans, 1165
 - for group incentive plans, 1183-1184
 - of response to incentive plan, 645-646
- Media, selection of, for advertising, 50-53
- Medical department, 1253-1255
- Medical service, industrial, 828, 1256-1261
- Merchandising, adding new items or lines, 75-76
 - all lines of business need, 79-80
 - changing size or quantity, 73-74
 - changing style or design, 72-73, 84-85
 - consumer demand, factors in, 80-81
 - definition, 68-69
 - department store, 278-288
 - developing new uses of product, 71-72
 - finding out what consumer wants, 82-88
 - main steps in, 80
 - manager, 89-90
 - methods listed, 70
 - objectives in, 69-70
 - organization of activities, 88-90
 - origin of problem, 68
 - price lines, 77-78
 - product association, 76
 - product improvement, 71
 - reducing or simplifying lines, 76-77
 - sales value in name, 75
 - servicing, 79
 - standardizing quality, 77
 - style indexes and statistics, 88
 - supplying directions for use, 78-79
 - testing consumer acceptance, 85-87
 - trends in product adaptation, 81-82
 - use of color, 73
 - use of sales statistics, 87-88
 - using waste or by-products, 78
- Mergers, case illustrating principles of, 502-503
 - decrease of total sales in, 496-497
 - defined, 467, 490
 - development expense for, 498-499
 - earnings of individual concerns, 486-487
 - economic and legal soundness, 483-485
 - effect on executives, 494-496, 1497
 - every case different, 482-483
 - excess of assets in, 497
 - excess personnel, 485-486, 499, 1312
 - financial position of, 486-487, 492, 499
 - financing of, 434-435, 438-439
 - formula or plan of, 487-488
 - importance of budget, 488-489
 - importance of human factor, 482, 495-496
 - increase administrative expense, 494-496, 501
 - international factors, 489
 - losses incident to, 496-500, 502
 - management of, 485-486, 492, 494-495, 498, 501
 - new investment and moving expense, 497
 - not a panacea, 484-485, 493-494

- Mergers**, production economies in, 500-501
 reasons for, 490-493
 sales economies in, 501
 uneconomical tendencies of, 493-500, 502
 use of committees, 488-495
